Too often we have achieved too little because we have attempted too much. If the layman is to read, to understand, to remember, and finally to employ our information and advice, we must not confuse him or tax his memory with more than the barest essentials. This rule applies to the great majority. On the other hand, there are some who will read the most lengthy and detailed health literature and believe themselves capable of lay diagnosis and self-medication.

There is an old rule of economics, "good enough is best." More than that is too costly and thus inefficient.

Let us try then to select and disseminate "that minimum of information which may provide a maximum of usefulness."

SALLY LUCAS JEAN, R.N., F.A.P.H.A.

Consultant in Health Education, National Foundation for Infantile Paralysis, New York, N. Y.

Thirty years ago Health Education was a new term. Now this new tool for the promotion of public health is universally accepted.

Health education involves people. It converts them to accept scientific health

knowledge with such confidence that they will discard hearsay and tradition and adopt for their personal use only those health practices which have a scientific basis. As citizens they will be so concerned with the value of modern

health measures that they will make their voices heard at the polls and in the halls of legislation where many of the public services affecting our environment are determined.

Health knowledge is important to bring this about but knowledge alone is not enough, there are other factors to be considered. Excellent papers on all phases of health are submitted by students whose living habits continue unaffected. A few years ago a high school girl in the Philippine Islands wrote a splendid term paper on beriberi. She presented accurate statements as to whole grain rice and other easily obtainable foods as preventives just two weeks prior to her death from the disease.

A teacher in the New York City schools died within the last three years of hydrophobia, declining to accept treatment for rabies while there was still time for it to be effective. There were 16,192 cases of diphtheria in the United States reported in 1946, though a preventive has been easily procurable for twenty years.

The Philippine student, the teacher, and the parents of diphtheria patients had knowledge, yet had not been sufficiently impressed by the facts to apply them.

Training in health matters involves the creating and developing of attitudes favorable to the acceptance of such knowledge at a time when a readiness exists. Then, too, the process of educating youths in health varies with sex, age, and experience.

Experience probably influences health practices to a great extent. Health education attempts through every medium known to furnish information and to create receptive attitudes toward health facts, utilizing planned and incidental experiences.

Propaganda is often mistaken for education, and there is a legitimate place for propaganda in arousing interest in health; but in education the learner is active while in propaganda the recipient is passive.

In each generation the people have had to be educated to disbelieve much of the teaching of their progenitors and to accept newer knowledge. This is a laborious process. When youths can be so instructed that they will develop confidence in well documented scientific facts and be prepared to accept new truths, the health education of adults will be greatly facilitated but we will always have to develop those attitudes and interests which motivate sound health practices.

BLEECKER MARQUETTE, F.A.P.H.A.

Executive Secretary, Cincinnati Public Health Federation

Health education is many things—not one.

To the teacher of physiology, it is giving instruction about the body and its functions. To the teacher of civics, it is the study of community health facilities and needs. To intelligent parents, it is guiding their children from birth in the knowledge and practice of sound habits of mental and physical health. To the public health minded

doctor, dentist, nurse, it is instructing patients as they see them in homes, offices, clinics, and hospitals in the prevention of disease and in the ways of health. To the health officer, it may be primarily acquainting the public with the methods by which his health department works for their protection and developing citizens' support for an adequate well staffed department.

To those concerned in a broad pro-

gram of health education, it means all processes by which citizens are taught essential truths about health with the specific purpose of: (1) Instilling habits of living that will promote physical and mental well-being. (2) Acquainting the public with health activities and health needs and developing support for a sound and comprehensive health program for the community, the state, and the nation.

But not all health education is of this beneficent type. The advertisement which subtly persuades the obese to use reducing drugs; the radio "plug" that makes a convincing appeal for a dentifrice guaranteed to whiten the teeth or retard caries; the movie that gives a completely distorted conception of psy-

chotherapy; the cultist who advertises some panacea to cure all ills; the quack, the nostrum vendor, and even the backwoods housewife who earnestly advises cobwebs for cuts and burns—all this is health education in reverse, but health education nevertheless. It is not to be discounted when we speak of education about health because these forces make a powerful appeal to the emotions and often with consummate skill. They exploit human desire for the easy way and the simple remedy.

One of the tasks of true health education is to offset these negative influences. Until we do, we shall never put fully into effect the invaluable tools for health that medical science continues to give us.

LUCY S. MORGAN, PH.D., F.A.P.H.A.

*Professor of Public Health Education, School of Public Health,
University of North Carolina, Chapel Hill, N. C.*

Through the years, definitions of health education have been more or less influenced by prevailing concepts in the two fields concerned—health and education.

Some persons have visualized health education as classroom instruction; others have thought of it as medical inspection in the schools, sanitary inspection of the environment, or physical education; others have seen it as publicity, a visit from the public health nurse, or listening to a lecture; and still others have encompassed the entire school or community health program in their interpretation of the term. Individual definitions have varied from the specific to the all-inclusive; but in an atomic era, when man's concern lies in *world* health, it is logical to seek a definition in terms of a total health education program for *all* people, and to attempt to find a mooring for it in the natural laws of human existence.

It is man's fundamental right to achieve the maximum health for which he is biologically capable, but to attain this he must learn to cope successfully with his physical and social environment. In the past such an adjustment to living has not been possible, because scientific knowledge has not been translated into everyday language and action. Therefore, one of the immediate objectives of a total health education program is to help bring scientists, educators, and laymen together so that each will understand the other and so that all can learn to work as a unit toward a common goal—positive health for *all* people. In addition to being concerned with this immediate objective, health education must help man to understand the problems of human behavior in relation to the uncompromising laws of nature and must help him recognize his importance in the universal scheme.

Such a program of health education,

or education for living, calls for a re-direction of the teaching of health and education, away from peripheral specialties and superficial efforts in organization and techniques, to a program which will apply scientific knowledge to

everyday living and make it possible for each individual to become a contributing partner in a world where not only man's health but his very existence depends upon his opportunity to think, observe, and plan in terms of all people.

DOROTHY B. NYSWANDER, PH.D.

School of Public Health, University of California, Berkeley, Calif.

Health education has become an ambiguous term, signifying to one person the health teaching procedures which are carried out in behalf of people; to another an intangible summation of experiences which have left their mark on a person's behavior with respect to health. Still a third concept is that health education is a process of change within the human organism itself which is related to achieving personal and community health goals. It is to this third definition of health education that this writer subscribes.

The question seems to be this: Is health education synonymous with health teaching or is education in health (health education) a process of learning (a process of self-building)? Teaching and learning are not the same thing. In the last analysis learning takes place only through the efforts of the learner. Thus, health education cannot be "given" to one person by another; it is not a set of procedures to be carried out or a product to be achieved; rather it is a dynamic ever-changing process of development in which a person is accepting or rejecting new information, new attitudes, and new practices concerned with the objectives of healthful living.

This is not quibbling with words. It is a difference which suggests that health teaching must be focused on *providing situations* conducive to learn-

ing. It is a difference which indicates that our emphases in a program of health teaching must be changed from attention to what is being done by the teacher to what is happening in the learner. Thus, the techniques for teaching health take their proper place as aids to facilitate learning, and their use will depend upon the degree to which they help a person in a given stage of the learning process. Some teaching aids impart authentic information; others develop motivations and desires to take action; still others enable the learner to participate in activities which bring satisfaction in their doing.

The armamentarium of the health worker, then, be it a scientific lecture, film, exhibit, pamphlet, conference, demonstration, discussion technique, or group planning activity, needs to be assessed as to its appropriateness in contributing to the development of a person in the stage of learning at which he finds himself.

If a "program of health education" means a program of providing situations for people in which, as learners, they "educate" themselves, then we have no quarrel with such a program. If on the other hand a "program of health education" implies that the health worker using his bag of techniques is doing the educating we must seriously disagree.

W. W. PETER, M.D., DR.P.H., F.A.P.H.A.

*Director, Training Division, Institute of Inter-American Affairs,
Washington, D. C.*

1. Health education is a means of persuading people to understand, accept, and apply that which will help them to live joyously, and productively, and to keep free from mental and physical deterrents for as long as possible.

2. Under an absolute dictatorship, volunteer health education would have no place whatsoever. To improve individual and community health, perhaps for military purposes, the dictator would merely issue commands to his subjects to do certain things, or else. This fantastic possibility has not yet been dramatized by some frustrated health educator discouraged over having to live in a democracy whose citizens pay him too little mind and consequently live incompletely and die prematurely. Regimentation may have its good points.

3. But for free people, obliged to make many decisions daily to do or not to do this or that, to shape their mode of living, education in health is one of many things to which they must be exposed, whether it takes or not. That is where the trained and skillful health educator comes in to provide subject matter and some sugar coating, an overall plan and individual incentive, plus occasional arresting devices to compete with other claimants for attention in a bewildering world.

4. When health education is aimed at the individual, it is with the hope that he will manifest his enlightenment by better personal health habits. When directed at communities a majority acceptance is sufficient. The unresponsive minority otherwise engaged will enjoy the new benefits anyway.

5. Health determining factors vary. In some parts of the world health education must begin with sanitation of the environment. Elsewhere, these problems have been replaced by others, including the distribution of medical care, the degenerative diseases, and problems affecting an aging population. Health education is not static. It is ancillary to scientific progress. Every now and then discoveries are made of important health significance. Potential beneficiaries must depend upon health educators in various guises to serve as transmitters between producers and consumers. Thus, health education is an important means of helping people achieve a higher level of living.

6. The real test of health education work is not how attractive are the hook and worm, but how many fish are caught; not how varied or fancy the sales techniques, but how many people bought the product for themselves, and are so satisfied that they tell their neighbors the good news.

CHARLES C. WILSON, M.D., F.A.P.H.A.

Professor of Education and Public Health, Yale University, New Haven, Conn.

Health education is an instrument which society uses to help assure individuals the benefits of modern medicine and public health. It helps them to understand themselves as living or-

ganisms and to become familiar with the various influences that affect health. It acquaints them with community resources for protecting and improving health, and helps them to solve individ-

ual and community health problems. Health education, therefore, is a means of securing widespread understanding and utilization of modern knowledge concerning health promotion and disease prevention.

What Is Health Education? may be answered by the following definition: Health education is the process of providing experiences for children and adults for the purpose of favorably influencing their knowledge, attitudes, and practices relating to health. Elaboration on the meaning and significance of certain words in this definition will help to clarify the nature and scope of health education as well as the total implications of the definition.

The word "process" indicates that health education doesn't just happen; it is carefully planned and efficiently conducted, with appropriate consideration of ultimate goals and of the best means for reaching them. Although unplanned experiences contribute to an individual's education relating to health, the teacher or health educator is concerned with supplementing incidental experiences with those that are carefully selected for their known value in attaining specific goals.

"Experiences" is used in keeping with present-day concepts of how individuals learn. The health educator and teacher are concerned with providing numerous and varied experiences and their work involves using all the techniques in the educator's armamentarium: reading and discussion, projects and re-

citations, audio-visual aids and problem solving, lectures and conferences, visitations and debates. The experience may take place in a classroom or conference, in the hospital or physician's office, in a committee meeting, or at home. Regardless of the technique used or the place where the experience occurs, the health educator is aware that interest and active participation facilitate learning. The student, whether child or adult, is given opportunities to share in planning and to "learn by doing."

The words "knowledge, attitudes, and practices" indicate three aspects of learning, each of which is important in health education. We are concerned with what individuals know, how they feel, and what they do. Influencing a person's health interests or attitudes, or changing his behavior, are just as important as helping him to secure understanding. Actually, knowing, feeling and doing are so closely interrelated in the learning process that it is almost impossible to separate them, except for discussion purposes.

Obviously, the word "health" refers to a condition of the total individual, and has physical, mental, emotional, and social components. Furthermore, health is considered a resultant of inherited endowments and of such environmental factors as personal and community health practices. Important goals of health education are to help each individual develop desirable personal health practices and to share in community health efforts.

Health Goals for Housing*

C.-E. A. WINSLOW, DR.P.H., F.A.P.H.A., *Chairman*

*Committee on the Hygiene of Housing, American Public Health Association,
New Haven, Conn.*

OBJECTIVES OF THE COMMITTEE

THE Committee on the Hygiene of Housing was established in 1937, at the request of the Housing Commission of the Health Organization of the League of Nations, and as one of the national committees corresponding with that Commission. Since that time it has served as the active housing arm of the American Public Health Association, and as a national clearing agency on health aspects of housing.

The committee's work is addressed to basic problems having practical significance for housing, nationally and internationally. Its aims have in the main been twofold: (a) to develop technical and administrative tools for housing improvement: standards for housing based on public health knowledge, means for evaluating departures from such standards, and legal and administrative procedures for the regulation and improvement of housing; (b) to enlist the interest of housers in health and of health workers in housing, and to promote coöperation between these workers and related groups in a comprehensive attack on the housing problem.

The members of the committee include representatives of public health and housing administration, city planning, sanitary engineering, architecture and construction, heating and ventilating research, sociology, home economics, research in statistical methods, and the law.

Programs are laid down and general policies shaped at annual or semiannual meetings of the full committee. Investigations are carried out by research subcommittees (including coöpted expert members from pertinent special fields), which conduct interim work-meetings as needed and are serviced by the committee's full-time staff.

The first adventure of the committee was the preparation of a report on "Basic Principles of Healthful Housing" (first published in 1938, with a slightly revised version in 1939). This report outlined in specific form thirty essential health needs which must be met if the dwelling is to provide a healthful environment for the family of the future. These are grouped under the four headings of Fundamental Physiological Needs, Fundamental Psychological Needs, Protection Against Contagion and Protection Against Accidents. This pioneer effort has been received with gratifying interest and has been generally accepted by authorities in many countries. It has recently been chosen by the American Institute of Planners as one of two American documents to be translated into Spanish, Russian, and other languages.

The committee next set about the expression of these Basic Principles in more concrete terms of performance through which the aims of adequate housing could be implemented by health officers and by public bodies and private groups and individuals interested in one

* Approved by the Committee, March 8, 1947.

way or another in the erection of future dwellings. Many collateral studies were carried out, some of which are described in a book, *Housing for Health*, in 1941, embodying the results of a conference called by the Milbank Memorial Fund. The major lines of work undertaken will be discussed in succeeding paragraphs of the present report. After ten years of the life of the committee, it seems timely to review our accomplishments and to chart our general course for the future.

This is particularly important, since the committee seems to stand today on the threshold of greater opportunity. Thanks to the continued generous support of the Milbank Memorial Fund and to the contributions made from time to time by other foundations and agencies, we have kept the ship afloat, although sometimes with anxious and difficult moments. The loyal support of the headquarters office of the American Public Health Association, the widespread and enthusiastic support of our efforts from the U. S. Public Health Service, city and state health officials, housers and planners, and the dawning interest in our work in other countries, gives us confidence that this work will continue—and on an expanded scale.

The program presented below embodies five major lines of activity, all more or less clearly visualized in earlier memoranda, but presenting, in greater or less degree, immediate challenges for the future. These objectives must be considered somewhat in detail. In many cases a present or clearly impending pressure on the committee from outside sources, growing out of recognition of past achievements, has been brought to our attention.

I. Measuring the Quality of Existing Housing

A central question in any program of housing improvement is: How bad and how extensive are the conditions to be

remedied? The health deficiencies and general quality of housing in slum areas must be measured objectively if enforcement policies of local health and building departments are to be intelligently shaped, and if rehousing programs are to meet real needs. At the time of the committee's inception no adequate method for such measurement existed. The survey procedure most widely used by housing authorities in judging the need for public housing has been the Real Property Inventory, a method of very limited usefulness because of the few factors covered and dependence on subjective schedule items. Inspection data from local health and building departments have usually been even less helpful to the housing agencies, because problem areas have not been systematically covered, because of unclear inspection forms, lack of any qualitative summation of the findings, and other factors.

In response to requests from health officials and housing authorities, the committee has concentrated a major part of its effort in the past several years on developing an inspection and appraisal method to meet this need of both enforcement and reconstruction agencies.

The appraisal method provides for observing a sufficient number of objective factors in housing quality to permit conclusive judgment as to the healthful adequacy of individual dwellings and of entire problem areas. The measurement of housing quality is expressed through a system of scores which has been thoroughly tested and has gained the approval of competent statisticians in the field of scale measurement. The results are finally expressed in the form of quantitative penalty scores and of specific basic deficiencies. The latter can be immediately used by the health department or other regulating authorities for rehabilitation orders or condemnation. The penalty scores, when

plotted on a map, provide the planner and the housing authority, as well as the health officer, with invaluable data for long-range policies.

The appraisal procedure was prepared with the greatest care and with the counsel of the best available experts. It was tested and retested on a practical scale and finally embodied in three monographs: one on the general philosophies and procedures involved, one on the appraisal of the dwelling unit itself, and one on the appraisal of the environment—a wholly new contribution to the housing problem. The first of these three volumes was issued over a year ago, the second will be issued in the immediate future, and the third is complete in manuscript and only delayed by shortage of staff at the printers.

This part of our job is done; and the reception of the appraisal procedure has been more enthusiastic than we had dared to hope. It has been officially used in Brookline, Mass.; in various small semi-rural areas of Connecticut; in Los Angeles, Calif.; Milwaukee, Wis.; New Haven, Conn.; Philadelphia, Pa.; Portland, Me.; St. Louis, Mo.; and Washington, D. C.—as well as in Panama City, Republic of Panama. The studies at Los Angeles and Milwaukee have already been conducted for over a year.

In these cities the findings are being used as the basis for the coördinated administrative policy of official agencies. Philadelphia, after a preliminary trial, has embarked on large-scale use of the technique to guide its ambitious program of urban redevelopment. Wherever it has been really tested this appraisal method has won ardent converts; and the U. S. Public Health Service is making earnest efforts to promote its use throughout the country.

We have now an acceptable, and accepted, measuring stick for the substandardness of housing.

II. *Establishment of Standards for Housing of the Future*

Our second problem, in a sense complementary to the first, was the formulation of broadly conceived but specific standards of performance for the new housing to be constructed in the years to come. We instituted this project in 1944 by the appointment of four subcommittees, to deal respectively with the Neighborhood as a suitable environment for the home, the Occupancy Standards involved in planning the dwelling, the Construction of the home and its Equipment. These subcommittees, under the chairmanship, respectively, of Frederick J. Adams, James Ford (succeeded by Clarence W. Farrier), Henry S. Churchill and Helen W. Atwater (succeeded by Mary Rokahr) have attacked their problems effectively. We have recently decided to concentrate the last two of these reports into one so that the final series will include three volumes, as follows:

1. The Neighborhood Environment of the Home
2. Planning the Home for Occupancy
3. Construction and Equipment of the Home

In each of these three monographs it is hoped to formulate definite and specific performance standards with regards to neighborhood and site planning, planning of the home itself for occupancy and construction, and equipment of the home. "Standard" requirements will be suggested which should govern all new construction; and, where appropriate, a "lowest tolerable minimum" (failure to meet which would justify legal action for rehhabilitation or condemnation) has been indicated; also, at times an "optimum," desirable where financial resources make it possible to exceed the "standard."

In the preparation of this series of monographs, we have been fortunate in the coöperation of the National Housing Agency, which during the past fall and

winter worked with us closely and intimately so that our joint conclusions will have assurance of official backing.

Volume I of this series, dealing with the Neighborhood Environment of the Home, was approved for publication at the March meeting of the committee. The preparation of the other two monographs is now our primary task and it is hoped that this task may be completed by the close of the calendar year. It is vital that the work be accomplished without delay, since so much of the home construction now under way is of so poor a quality as to constitute little more than an addition to our slum problem.

III. *Strengthening and Clarification of Housing Regulation and Their Enforcement*

A third major project, envisaged in our earlier memoranda, was the study and improvement of practice in the field of housing regulation by health departments and other official bodies. In this field there is a considerable amount of valid precedent. Though out of date in some particulars, Veiller's Model Housing Law of 1920 (adopted in whole or part by several states and cities) is a landmark of constructive thinking and sound practice. In the two decades since Veiller, many kinds of specific regulation have been developed for particular local needs, and various devices for improving enforcement practice or clarifying administrative responsibility have been tried.

The total picture of housing regulation, however, remains chaotic. Laws or ordinances are developed in one place and slavishly copied in another, where conditions may be wholly different. Requirements for new dwelling construction are generally buried in building codes, where preoccupation with the structural requirements of many other types of buildings results in neglect of fundamental health requirements such

as protection of water supplies and sewage disposal, adequate spacing of buildings, reasonable room sizes, or even the requirement of basic heating and sanitary facilities.

In most communities the requirements for existing dwellings (maintenance of repair, permitted occupancy, services required in multiple dwellings, etc.) are both archaic and uncoded. Scattered through many ordinances and codes, they are hopelessly obscure as a basis for enforcement even where their provisions are reasonably in line with modern thinking.

From its earliest days, the committee has been repeatedly approached by local and state health officials and by the national housing and public health agencies for advice or assistance in framing or revising regulatory housing laws and ordinances, in order that these might reflect contemporary health criteria of housing adequacy.

In response to such requests the field of legislative control has been recognized as the third concentration area for the committee's investigative effort, and basic studies addressed to urgent practical problems in this field have been initiated.

It has seemed to the committee desirable to differentiate, in our initial approach, between Building Codes, designed to cover the erection of new structures, and Housing Codes, governing action with regard to rehabilitation or condemnation of existing dwellings. We recognize that some states have "Housing Codes" dealing with both new and old dwelling structures. On a local level, however, this combination rarely exists; and for the present discussion, we shall use the terms as defined above. In this sense, the Building Code normally deals with all structures, including dwellings, and is commonly enforced by a building department. The Housing Code, in the sense in which we have used the term, deals with occupied

dwellings and—in large measure—with conditions of dilapidation and occupancy. Yet the two fields are obviously closely related. In both instances, three different problems are basically involved:

1. What should be the basis, in administrative law, upon which such codes should be established and how specific should they be, that is, how far should authority on detail be delegated to the enforcing agency?
2. What specific body or bodies in a municipality should exercise the power of preparing such codes and enforcing them?
3. What should be the substantive content of such codes?

The subcommittee appointed to deal with this problem, under the leadership of Charles S. Ascher, has made substantial contributions in several brief reports on the first of these questions. In an address on "The Regulation of Housing," delivered at the Inservice Training Course in Housing at Ann Arbor last August, he presented an admirable exposition of the subject and demonstrated his conviction that housing regulation should be accomplished—not by expansion of the general powers of the health department to control nuisances under the common law, and not by invoking the right of eminent domain, but by the adoption of a single uniform code dealing with all aspects of health and safety under the police powers of the community. The substance of Mr. Ascher's article, if presented in more formal terms, would be an excellent report for our committee, and we hope that it may be developed in such fashion during the next few months. It is hoped that the report may point out the extent to which it should be possible to reduce both Building and Housing Codes to relatively simple performance standards, delegating to the enforcing authorities the power to determine the degree to which particular conditions meet such broad performance standards.

The minuteness of the specifications

in many present codes is nothing less than fantastic, and works incalculable harm by freezing someone's haphazard judgment of the moment into shackles which may impede sound engineering progress and increase construction costs for decades to come.

A second vital point relating to administrative machinery for enforcement is indirectly answered by Mr. Ascher's subcommittee in the recommendation that the Housing Code be framed by a committee to be set up in a given community to represent various agencies involved in housing supervision. Professor Spencer Parratt, in a valuable recent paper on "Administrative-Legal Methodologies in Elimination of Substandard Housing,"* appears to favor transferring all such powers to a separate housing administration. The health department, however, has certain fundamental day-by-day responsibilities with regard to health which can scarcely be abrogated. It is fundamentally bad administration to have two or more sets of inspectors routinely visiting the same premises for closely allied purposes. It would seem wiser, instead of introducing a sixth new agency in the regulatory field, to suggest a procedure by which the health department, the building department, the fire department, the police department, and the zoning board would coöperate in framing both Building and Housing Codes. Special legislation might be desirable which would permit the issuance of jointly supported Building Codes and Housing Codes, but in any case the existing powers of health departments to draft housing regulations having the force of law should be preserved.

The Building Code might logically be enforced by the building department, which grants permits for all new structures, while the Housing Code might

* *Law and Contemporary Problems: Housing*, School of Law, Duke University, Vol. XII, Winter, 1947, p. 110.

primarily be enforced by the health department (with the building and fire departments coöperating where desirable). In any case our committee should decide on a recommended policy—or alternative policies—and formulate its conclusions with a minimum of delay.

Finally, the third problem—that of the substantive content of a Housing Code—has not as yet been attacked effectively by our committee, although the appraisal procedure and the “minimum tolerable” conditions in our monographs on standards for future housing furnish much of the material needed for such a code.

Action in this field—and prompt action—seems to be of vital importance. It has therefore been decided to appoint a new Subcommittee on Substantive Content of a Housing Code. This subcommittee will be headed by Health Commissioner E. R. Krumbiegel of Milwaukee, and should include representatives of the fields of building inspection and fire protection. Our present Subcommittee on Housing Regulation should attempt to answer question 1 above. Both subcommittees should coöperate in answering question 2. The new subcommittee should deal with question 3.

In regard to questions 1 and 2, our subcommittees might properly deal with both Building and Housing Codes, but in approach to question 3 we believe that we should, first of all, approach the question of the substantive content of the Housing Code. There are three reasons for this order of approach. In the first place, Housing Codes frequently fall within the direct responsibility of our primary client, the health officer, while Building Codes do not. In the second place, Building Codes are fully crystallized in forms which are generally archaic and inadequate but supported by powerful vested interests and traditions, while Housing Codes are either wholly absent or still fluent and can

readily be improved. Finally, perhaps the best way to approach the citadel of the Building Code is to establish good Housing Codes and then develop the deficiencies of the Building Codes by demonstration of the inadequacies and unreasonablenesses of their requirements.

IV. Promotion of Use of the Committee's Findings

The first three objectives which have been outlined all deal with the development of standards, procedures, and policies which we hope may be applied by others. Without such application, they are merely pious aspirations on paper. Our committee, although primarily a research body, has recognized from the outset both an opportunity and a responsibility for promoting wider understanding and habits of coöperative attack among those agencies and professions whose functions impinge on the public health aspects of housing. Such understanding and attack have been promoted first by the varied composition of the committee, whose membership brings together expert technicians and administrators from a dozen branches of the housing and public health movements, and second by the selection of its projects and the character of its open meetings, at which even wider groups have been convened to coöperate in the committee's program or to review parallel developments from other sources. A considerable list could be adduced of the significant lines of investigation by other groups, or of wholly new kinds of inter-agency coöperation which are directly or indirectly traceable to this conscious emphasis of the committee.

Certain main lines of essential public relations are clearly indicated, as follows:

A. Promotion of Use of the Appraisal Procedure:

1. To stimulate official and professional interest in the practical signif-

icance of the appraisal method by obtaining early publication in appropriate journals of the comparative results (graphically presented, with simple text) of three to five of the studies now completed or in process (Milwaukee, Los Angeles, Philadelphia, St. Louis, perhaps Washington or New Haven).

2. To extend the machinery available for local installations of the technique by carrying through with the U. S. Public Health Service contemplated training of housing specialist personnel of its district offices.

3. To interpret accumulating experience with the technique (for the general benefit of users and for needed adaptations to regional or other problems) by maintaining an advisory relation to the U. S. Public Health Service.

4. To promote the use of the technique, internationally, with suitable modification, by rendering consulting service as desired by foreign agencies (a forthcoming Spanish publication of a study at Panama is expected to create demand in Latin America).

5. To encourage inclusion in the 1950 U. S. Housing Census of improved schedule items or tabulation practices developed for this technique, by resumption of coöperative arrangement with the Bureau of the Census, with appropriate test studies of proposed Census material.

6. To adapt the procedures to rural or other special types of housing, by coöperative studies with agencies desiring such adaptation.

B. Promotion of Acceptance of our Monographs on Standard Housing by:

1. Complete and prompt publication of our scheduled reports on Occupancy, Construction and Equipment standards.

2. Furthering the acceptance of such standards by the building industry, the real estate groups, groups interested in the financing of housing and various public bodies with responsibilities for

housing supervision, through brief and popular summaries for their professional meetings and publications.

3. Promoting consumer demand for proper standards in housing, through non-technical articles in popular magazines of national circulation.

C. Strengthening and Clarifying Regulatory Housing Procedures by:

1. Publishing as a committee document the housing regulation subcommittee's findings and recommendations as to administrative provisions in housing control.

2. Publishing, in combination, or in series with the above, a statement of the essential substantive provisions of housing regulation—a statement which will carry to the point of quantitative specifications in so far as possible. The steady flow to committee headquarters of inquiries in this field indicates its growing importance to health departments, and suggests the urgency of committee publication. Release before the end of 1947 of both statements noted above—even though one or both may be provisional—should be considered most desirable.

3. Stimulating adoption of regulations embodying the principles developed, through joint efforts with the U. S. Public Health Service, state health departments, and other means to be explored.

4. Interpreting experience under such regulations, as a basis for future improvement thereof, through subcommittee contacts with adopting localities or states; and publishing from time to time such interpretation and suggested improvements as experience may warrant.

D. General Relations with the Public Health and Allied Profession:

If we are to attain the goals in view it seems important:

1. To stimulate the assumption by

American health departments of their full responsibility in broad housing programs, by creation of a subcommittee charged with exploration of this problem. Such a group would presumably consider means of channelling the technical output of the committee to health departments, but would be concerned with other matters also. For instance, what training should be offered in public health schools to provide personnel for the housing functions of health departments?

2. To promote the effective participation of health departments in the housing programs, by using available machinery of the American Public Health Association (Committee on Administrative Practice, Engineering and Health Officers Sectional organizations, *American Journal of Public Health*) as a channel for the procedures developed by the committee.

3. To stimulate the development of housing machinery within the World Health Organization, and through it the development of other national committees on the hygiene of housing; by calling attention to international interest of health agencies in the work and output of our committee, and by other means to be explored.

4. To strengthen interprofessional coöperation in the fields of housing, public health, city planning, and related academic disciplines; by systematic exchange of our publications with leading national and international bodies in these fields and by participation in their professional conferences.

V. Research

"Research" is a term not easy to define. Our reports, dating back to the *Basic Principles of Healthful Housing* have all been founded on research, and research not confined to the library but extending to important studies of air conditioning, illumination, and sound control in the field. Our appraisal pro-

cedure rests firmly on the basis of exhaustive field research.

It seems likely, however, that fundamental investigation must play a larger part in our future program. The preparation of the monographs on standards has revealed many serious gaps in knowledge which remain to be filled. Below is a list of certain specific topics which have been brought forcibly to our attention.

1. Determination of the most desirable levels of illumination for the performance of various household tasks, to resolve the present difference of opinion between psychologists and illuminating engineers in regard to this problem, presumably in coöperation with the Illuminating Engineering Society and other bodies.

2. A further definition of the noise levels compatible with human health and comfort (to perfect existing standards which have little substantial basis); and a study of the quality and effect of various outdoor noises and of the influence of site planning and natural barriers in reducing such noises.

3. A study of the influence of space allowances and space organization in the dwelling upon household operation, psychological reactions and emotional tensions, perhaps in coöperation with other organizations, including the National Institute of Mental Health.

4. A study of the influence of residential density upon the load on community facilities and the cost of such facilities, in coöperation with housing management and various specialized groups concerned.

5. A laboratory analysis of the basic factors in floor construction affecting safety and fatigue. This would involve the development of instruments for measuring both resistance and resiliency of flooring materials and psychological study of their effects upon the human organism.

6. Development of adequate techniques for the evaluation of the influence of good housing upon physical, emotional, and social health. A careful study of this problem is now being carried on by a special joint committee appointed by the American Public Health Association and the National Association of Housing Officials.

These are only a few of many suggestions which might be made. It seems desirable that the committee, in this field, should undertake:

1. To appoint a special subcommittee on housing research to formulate a series of the more important problems which call for solution, and to suggest the general lines along which such problems might be solved.

2. To foster needed further research in the field of housing standards, by systematic statement of those problems on which present knowledge is inadequate; with special reference to problems within the competence of the U. S. Public Health Service, American Public Health Association, state health departments, schools of public health or other health agencies.

3. To encourage a rational distribution of housing research effort, by exchange of information with other national bodies concerned with housing, public health, planning or other allied research (Social Science Research Council; U. S. Public Health Service; University of Wisconsin Conference on Housing Research; National Association of Housing Officials; technical divisions of National Housing Agency, Federal Public Housing Authority, Federal Housing Administration; National Research Council; Bureau of Standards, etc.; also similar bodies abroad).

4. To prosecute such studies as may be appropriate to the abilities and scale of the committee, by assignment of subcommittees and staff to selected investigations.

It is fully realized that such a program as that outlined will seem Utopian. Yet "a man's reach should exceed his grasp"; and the present progress of the committee's work would have seemed Utopian when the committee was established ten years ago.

We have, first of all, to apply our limited resources to the completion of our two unfinished jobs, the preparation and publication of the standards monographs and the development of official recommendations with regard to the methodology and substantive content of regulatory legislation.

We cannot promote policies we have not clearly formulated and adopted. Yet the formulation of policies is of limited value unless they are applied. If the general lines of activity outlined above seem sound to the committee, additional available funds will automatically determine their practicability.

But funds are rarely available without a bold and far-reaching program.

Control of Dengue in Hawaii

CHARLES L. WILBAR, JR., M.D., F.A.P.H.A.

President, Board of Health, Territory of Hawaii, Honolulu, T.H.

DENGUE fever appeared in the Territory of Hawaii in July, 1943, for the first time since 1912, and soon after its appearance reached epidemic proportions. Usually when dengue is introduced into a non-immunized community, particularly a community where mosquitoes live and breed all the year around, a majority of the population contracts the disease within a short time. However, only 1,498 cases of dengue occurred during this epidemic in the Territory, out of a population of approximately 500,000 persons. There is, consequently, good cause to believe that the preventive measures taken during this outbreak of dengue may have been responsible for controlling its incidence. All but two of these cases occurred in the city of Honolulu, the population of which is approximately 250,000.

After the epidemic phase, dengue continued to occur sporadically in the Territory. This paper deals with the epidemiological aspects of dengue control in the Territory both during the epidemic period and during the endemic period to date. Most of the dengue control measures have had to do with efforts directed at the elimination of *Aedes* mosquito, the vector of the disease, which breeds in the Territory throughout the year, although it is believed that efforts to obtain early diagnosis and proper segregation of persons so that mosquitoes could not bite them played a part in the successful control of the disease.

At the onset of the epidemic, the Honolulu Chamber of Commerce and the U. S. Public Health Service con-

tributed funds toward dengue control, and the Army was soon aiding in the control program by assigning considerable personnel and equipment to control work. At the request of the Territorial health department, the Public Health Service immediately flew to Hawaii an entomologist (Dr. Robert L. Usinger) and a sanitary engineer (Wesley E. Gilbertson) from the Atlanta office of its Malaria Control in War Areas unit. In March of 1944, Dr. Usinger reported on the entomological phases of the dengue epidemic in Honolulu¹ and in March of 1945 there was printed in the *American Journal of Public Health* Mr. Gilbertson's report on the sanitary aspects of the control of this epidemic.²

EPIDEMIOLOGICAL DATA

The epidemic phase of dengue ran its course largely during the fiscal year beginning July 1, 1943. The first two cases reported to the Board of Health had their onset of symptoms on July 24, 1943. Information concerning the 1,498 cases which developed in Honolulu during that year has been subjected to statistical analysis.

Although during the war years there were several times as many males residing in the Territory as there were females, 58 per cent of the cases of dengue occurred in females, and 42 per cent in males. The higher incidence of breeding of the daytime *Aedes* mosquito in and about residences compared to the business district may be the factor responsible for the preponderance of cases among females.

months, followed by a gradual decline throughout the following six months. Dengue has continued to occur sporadically in the Territory since then, although no cases have been reported to the health department since July, 1945.

Figure 3 indicates the weekly incidence of dengue along with the *Aedes* breeding index and the rainfall in inches during the epidemic period. Table 1 portrays numerically the weekly incidence of the disease during that period.

CONTROL MEASURES

Upon the outbreak of dengue the health department, with the cooperation of the Army authorities, the Navy

authorities, the U. S. Public Health Service, the Public Health Committee of the Chamber of Commerce of Honolulu, the Office of Civilian Defense, the government of the City and County of Honolulu, the Department of Public Instruction, and certain other governmental and private agencies, inaugurated a concentrated educational and publicity program to keep the civilian and military population of the Territory well informed as to the possible seriousness of an epidemic of dengue and how to prevent its spread. The control of the *Aedes* mosquito was stressed, both as to methods of destroying the adult mosquito and of preventing the breeding of this daytime vector.

This educational publicity took the form of (1) daily newspaper articles, (2) daily radio news broadcasts, (3) six 75 word spot announcements per day over Honolulu's two radio stations during the first month of the epidemic, (4) radio spot announcements in the Filipino language, (5) distribution of 30,000 multigraphed sheets on mosquito control, (6) a house-to-house educational canvass by the city's OCD wardens to search for mosquito breeding areas and to inform individuals as to mosquito control procedures, (7) special 15 minute radio talks by health department personnel on the subject of dengue, (8) talks by health department staff to various community clubs, (9) quarter-page advertisements on mosquito control in both Honolulu daily newspapers, and (10) publication and distribution of a leaflet in English, Filipino, Chinese, Korean, and Japanese.

The physicians on Oahu were requested by the president of the Board of Health by circular letter, as well as verbally at the regular monthly meeting of the Honolulu County Medical Society, to report suspected cases of dengue immediately upon discovery to the Board of Health.

In each instance, when the communicable disease bureau of the health department was informed of such a case, the bureau arranged to have a public health nurse and a mosquito inspector immediately visit the home of the suspect, look for breeding places inside that home and in the areas surrounding it, destroy such breeding places wherever found, thoroughly spray the home of the suspect with pyrethrum insecticide, spray the homes surrounding that of the patient with insecticide, and instruct the persons in the vicinity as to mosquito control.

Honolulu Advertiser Photo

FIGURE 4—Outdoor spraying with pyrethrum-base spray for adult mosquito destruction. Standard Army Chemical Warfare Sprayer being used; also utilized, with excellent results, were Bean Tommy Gun Sprayers with $1/32$ " orifice.

The Army loaned the health department a number of mosquito bed nets and, upon the visit of the public health nurse to the home of a suspect, she placed such a bed net over the sick person and instructed him how to use the bed net properly. This net was kept over the patient during the first four days of his illness, which is the period during which a mosquito can obtain the disease organisms from a dengue patient. The public health nurse also filled out the first part of an epidemiological report form, instructed the household in which the patient lived concerning precautionary measures, and helped to see that he obtained satisfactory medical and nursing care.

In the section of Waikiki where the outbreak originated, the following special precautions were taken: (1) the area was placed off-limits to all Army and Navy personnel who did not live or have official business in the area, and civilians were urged to stay out of the area in the daytime unless they had urgent business there; (2) mosquito control inspectors thoroughly searched the area for mosquito breeding places and eradicated those found; (3) with the aid of Army trucks containing high-pressure spraying apparatus, the whole area was clouded with pyrethrum insecticide under the direction of the mosquito control inspectors (Figure 4); (4) inspectors gave individuals in each household a mimeographed sheet of instructions concerning mosquito control, and verbally instructed persons in the household at the time of distributing the sheets; (5) personnel from the Office of Civilian Defense carefully checked all bomb shelters for mosquito breeding, destroyed the breeding places when present and thoroughly sprayed all such shelters with insecticide; (6) the Hawaiian Electric Company, the Mutual Telephone Company, and the Board of Water Supply checked man-holes and other installations in this

area for mosquito breeding places and stopped such breeding whenever it was found.

The Public Health Committee of the Chamber of Commerce of Honolulu, upon request at the onset of the disease, immediately made available funds to employ 24 additional mosquito control men to work under an employee on their pay roll who had been doing mosquito control work for a number of years and to work directly under the supervision of the bureau of sanitation of the Board of Health. Five soldiers trained in mosquito control were also loaned to the health department to work directly under the bureau of sanitation, and certain Army vehicles were assigned to aid in the control program. The Office of Civilian Defense loaned the health department two trucks for mosquito control work.

At the instigation of the health department, the Hawaiian Airlines agreed to spray thoroughly with insecticide the airplanes leaving Honolulu for other islands. The Army and Navy authorities immediately took action to see that military planes leaving the island of Oahu (on which Honolulu is located) were also sprayed in a like manner.

At the request of the health department the War Shipping Administration asked the masters of all interisland ships to look for mosquito breeding places before the ships left Honolulu and to spray thoroughly with insecticide the living quarters in the ships before the vessels left the port of Honolulu. The Army Transport Service issued similar instructions for its interisland ships and the Navy also took similar precautions.

The Army, Navy, and U. S. Public Health Service continued to emphasize the program which had already been in effect of thoroughly spraying with insecticide each airplane arriving in the Territory of Hawaii before the passengers left the plane, for the purpose of preventing the importation of any fur-

ther disease-bearing mosquitoes into the Territory. These organizations also sent quarantine officers aboard all incoming ships to look for persons with infectious diseases, including dengue. If any such persons were found they were immediately placed under quarantine.

The chief quarantine officer of the Public Health Service in the Territory arranged to have his personnel supervise a search for mosquitoes and mosquito breeding places on all ships leaving Hawaii for the mainland.

At the request of the Army, mosquito inspectors working for the Board of Health accompanied groups of soldiers in searching for mosquito breeding places for $\frac{1}{4}$ mile radius around each Army post in the city of Honolulu. Besides restricting the Waikiki area, the Army restricted areas of a radius of 800 feet around each case of dengue in the city.

The two U. S. Public Health Service officers, arriving within a week of the reporting of the first case of dengue, were empowered to expend Public Health Service funds, under the appropriation for Malaria Control in War Areas, for hiring additional mosquito control personnel and purchasing additional mosquito control equipment.

To each of the county health officers on islands other than Oahu were sent detailed instructions regarding inauguration of all possible mosquito control measures on those islands, which were immediately put into effect.

A program for the clean-up of dumps, dumping areas, and vacant lots in order to destroy probable mosquito breeding places was inaugurated by the health department.

Since the public schools were about to open, the president of the Board of Health was invited to meet with the Commissioners of Public Instruction to offer suggestions for the school department's participation in the control program. His requests were put into effect

by the commission, as follows: (1) Before the opening of the schools careful mosquito control activities were inaugurated in and about the school buildings. (2) Methods of control and spread of dengue were emphasized in classroom teaching when the schools opened. (3) The schools were used as a means of disseminating to the homes information on the prevention of the spread of the disease.

All key persons in the health department intimately concerned with dengue control met twice a week along with Army and Navy representatives to keep each other informed as to the details of what was being done to control the epidemic and to formulate plans for new action.

The engineer of the Public Health Service who was assigned to the health department was placed in charge of the division of mosquito control of the bureau of sanitation. By the middle of September, there were 103 men working in this division, employed by the Chamber of Commerce of Honolulu, the U. S. Army, and the U. S. Public Health Service. Each of the inspectors was provided with a kit, consisting of mirrors and flashlights to find breeding places of larvae, three types of larvicide for control work, educational pamphlets for distribution to householders, and report sheets.

The entire city of Honolulu was divided into 94 control zones, and an inspector was assigned to each zone. They were grouped into cadres of 6 to 11 men each, under 12 foremen. Three district offices were located in the city at the main health building and at the two major health centers of the health department. Inspectional activities were carried out on a cycle of not less than 10 days. A total of 13 vehicles were in use, provided by the health department, the Army, and the Office of Civilian Defense. An in-service training program for the newly employed

inspectors was in continuous operation. One hundred thousand copies of educational pamphlets on mosquito control were printed and distributed by volunteer groups to persons living in the rural areas of Oahu and on the other islands.

By September 13, 1943, acting in accordance with epidemiological and entomological data, the military authorities lifted the restriction on the Waikiki area. By that time, the outbreak had spread to a number of other areas in the city and was definitely on the wane in the Waikiki district.

A second major concentration of dengue cases appeared in a congested part of the city known as the Kakaako District. The first cases were reported from a large laundry located there. Soon so many cases were present that the Army put this district out of bounds to its personnel. By the end of October, when there were still many cases in the Kakaako District, another major focus arose in the congested area near River Street, which was in turn placed out of bounds by the Army for their personnel. This proved to be the last major focus in the Territory, and it never reached the incidence that was attained in the Waikiki and Kakaako areas. By the end of the year Army restrictions had been lifted from all areas.

Only two individuals developed dengue outside of the City and County of Honolulu. These cases occurred on the island of Kauai in December, 1943. The first person to develop this disease was a resident of Kauai who had been visiting in Honolulu and while there had lived in a house where another case of dengue had developed. After returning to his home on Kauai, this man developed typical symptoms of dengue. A period of $14\frac{1}{2}$ days had elapsed from the date of his departure from Honolulu until the onset of his sickness on Kauai. Owing to the conditions under which his disease developed, it can be stated that his incubation period was at least

$14\frac{1}{2}$ days, an unusually long incubation period for this disease. Ten days later another man living in the same house on Kauai developed dengue. From the time of the diagnosis of the first case on Kauai all precautions that were being observed in Honolulu were taken in the plantation village where this man lived, including covering the patient with a mosquito net, spraying the interior of the house where the patient lived and the exteriors of all buildings within a 500 foot radius of that house, and frequent inspections to eliminate mosquito breeding. No further cases have been reported from the island of Kauai.

Following the battle of Saipan the 5th Marine Division was sent to the island of Hawaii for a rest period. Upon arrival on Hawaii there were 26 marines ill with dengue. However, all of the individuals had been sick for at least 4 days, so that the period during which they could infect mosquitoes was passed. All individuals were isolated at the Marine Camp in an area remote from civilian population. Inspection of the area revealed no *Aedes* mosquitoes either of the *albopictus* or *aegypti* variety. No further cases of dengue developed among these marines nor did any cases develop among local inhabitants of the island of Hawaii.

During the early part of 1944 more and more personnel were assigned to the health department for mosquito control activities from the Army and from the U. S. Public Health Service, particularly from the former. The peak in the number of persons working on mosquito control in the Territory occurred in March, 1944, when 398 individuals were working under the health department on this activity. One hundred and ninety-nine of these were assigned to mosquito control activities in the city of Honolulu. With additional personnel the mosquito control program was extended to rural areas on the island

of Oahu and then to the other major islands of Hawaii, Maui, and Kauai. The breeding index of the *Aedes* mosquito, i.e., the number of premises found breeding this mosquito per hundred premises examined, was 10 per cent in the city of Honolulu at the outbreak of dengue, as determined by the health department's inspectional force. Concentrated efforts directed at mosquito control reduced this breeding index very quickly. By August 31, 1943, the index was 5.7. By September 30 it had dropped to 1.7. It remained a little over or below 1 for the rest of the year following the outbreak of the disease except for March, 1944, which was a particularly wet month, when it showed a rise to 3.5. Reductions in breeding indices on other islands and in rural Oahu were also accomplished by mosquito control activities, but not quite to the remarkable degree of reduction which took place in Honolulu, where nearly all of the cases of dengue occurred and therefore where the major continued concentrated mosquito control activities have been in effect.

Some control activities aimed at reducing the incidence of the night-flying, singing *Culex* mosquito were incidentally inaugurated under the mosquito control program for fighting dengue. While the *Culex* does not carry dengue and is not considered a potential spreader of disease in Hawaii, it is a considerable nuisance. Consequently, when *Culex* were found to be breeding in premises visited, measures were taken to prevent this breeding and householders were instructed as to control methods against this species. The *Culex quinquefasciatus*, the type found in Hawaii, tends to breed in large areas of water, such as polluted ponds, streams, and swamps, and is not therefore a domestic type of mosquito such as the *Aedes*, which breeds in and around houses in the small quantities of standing water often found in tin cans, bottles, and certain types

of plants. In controlling the *Culex*, swamps and streams have been sprayed with larvicide and stocked with mosquito fish, particularly with *Gambusia minnows*. Some streams have been cleared and a few swamps drained. Considerable reduction in the breeding index of the *Culex* mosquito was obtained with a consequent decrease in the number of complaints received by the health department about this nuisance insect.

In spite of the abatement of dengue in epidemic form, a major mosquito control program was continued in the Territory with federal assistance throughout 1944 and 1945. With the cessation of hostilities, a gradual reduction of military personnel working on mosquito control took place until by November, 1945, all soldiers had been removed from this program. The support of the U. S. Public Health Service was continued until the end of May, 1946, when that federal support also was withdrawn from the Territorial mosquito control program. Since that date there has been maintained under Territorial funds a minimal mosquito control program in the cities of Honolulu and Hilo, aimed mainly at the control of the *Aedes* mosquito, the spreader of dengue fever. This program is effectuated by approximately 30 persons and is maintained as a subdivision under the bureau of sanitation. Inspection units comprise a nucleus of well trained men who, in the event of another serious outbreak of dengue, could train additional workers and direct expanded mosquito control activities. These units can be sent to any part of the Territory where an outbreak of mosquito-borne disease might occur. Pyrethrum and DDT larvicides and adulticides are being widely used. The health department entomologist is doing continued research concerning methods of improving the dispersing of larvicide and of effectively eliminating breeders. Attempts are also being made

TABLE 2

to determine the effect of DDT and other larvicides on beneficial insects. Educational work on mosquito control is being continuously promoted, both on the adult level and throughout the school system of the Territory.

Table 2 shows the monthly incidence of dengue cases reported to the health department from July, 1944, to June, 1946. Cases are divided into civilian and military, and into those which were acquired within the Territory and those which were acquired outside the Territory, the latter being officially designated as "off-shipping" cases. The last case was reported in July, 1945.

DISCUSSION

It cannot be said that mosquito control activities and other measures to control dengue which were inaugurated at the onset of the epidemic in the Territory in 1943 and the abatement of the epidemic after only approximately 1,500

cases had occurred were assuredly cause and effect, since we were not dealing with a controlled scientific experiment but rather with an epidemic of a usually rapidly spreading disease among a group of humans in a forward area during a major world war. There is, however, much to indicate that the control measures actually did stop this epidemic in its tracks. In 1943 dengue was introduced into a non-immune population in Hawaii and into an area where there was a high *Aedes* mosquito breeding index occurring all the year around. Thus, factors were present conducive to the rapid spread of dengue to a great majority of the population in the built-up areas of the Territory. This has been the history of this disease heretofore when newly introduced into a community.

Not only were tried and true methods of mosquito control applied in a concentrated fashion to the city of Hono-

lulu and later to other areas of the Territory, but two new methods never before utilized in controlling widespread dengue in a community were inaugurated; namely, fogging the atmosphere with power sprays of insecticide and the use of a newly discovered and remarkably effective insecticide, DDT.

In peacetime it would be unlikely that health authorities could ever persuade the holders of public purse strings to expend enough funds to employ nearly one individual per 1,000 population for mosquito control in order to prevent the spread of a disease such as dengue. During a war, however, expenditures on a grand scale are the order of the day and a more intensive program to protect the health of a community having a vital part in the furtherance of that war could be put into effect than would normally be true. If a half or even a third of the military and civilian population of the Territory of Hawaii had been stricken with dengue in the summer of 1943, it is quite possible that the war effort in the Pacific would have been seriously hampered. Even in peacetime the expenditure would be economically sound, for the cost of having several hundred thousand persons sick with this disease for an average of 2 weeks per person would be considerably greater than the cost of control measures at \$2 to \$3 per person per year.

The need for a continued mosquito control program in the Territory is almost self-evident. Without continued education and surveillance concerning the control of the *Aedes* mosquito, the high prevalence of this insect in the Territory throughout the year would recur and the reintroduction of dengue into the community would in all probability soon result in a rampant spread of the disease into another epidemic.

Should such a situation arise, there is no longer the former large military

population or large war fund to which we could turn for aid in controlling the epidemic. There is every reason to believe that with increased incidence and speed of air travel between Hawaii and areas west of here, where dengue is present at all times, persons will be arriving in the Territory from time to time during the incubation period of the disease and developing clinical symptoms here. Although there is maintained a thorough program of spraying airplanes arriving in the Territory from other areas in order to kill all mosquitoes on board, it is still possible that some infected mosquitoes may be brought to Hawaii by airplane. With a low incidence of the mosquito vector of the disease, however, these sporadic arrivals should not cause the disease to become widespread among the inhabitants of our Territory.

SUMMARY

An epidemic of dengue fever started in Hawaii in July, 1943, when the Territory was an important military center of the war. Previously there had been no dengue reported in the Territory since 1912; consequently, no immunity to the disease was present in the population.

Owing to the danger that a widespread incidence of dengue would seriously hamper the war effort, an unusually vigorous attack was made upon the disease by both civilian and military personnel, under the guidance of the Territorial Board of Health. At one time 398 persons were assigned full time to mosquito control activities. One hundred and ninety-nine of these were working in the city of Honolulu. Nearly all mosquito control personnel were soldiers or were employed by the U. S. Public Health Service, although at the beginning of the epidemic emergency funds were used by the Honolulu Chamber of Commerce to hire men for mosquito control work.

During the year-long epidemic, only 1,498 cases of dengue were reported to the health department out of the Territorial population approximating 500,000 civilians and many thousands of military persons. All but two of these cases occurred in Honolulu. The usual history of dengue newly introduced into a community where the *Aedes* mosquito thrives has been a spread of the disease until 50 to 75 per cent of the population have contracted it.

The *Aedes* mosquito, carrier of dengue, was attacked by all known methods of mosquito control, including the use of DDT as soon as it became available. In addition, the atmosphere was fogged with insecticide around the homes of dengue patients, using high pressure Army sprayers attached to tank trucks.

An intensive educational campaign accompanied the activities of the mosquito staff and consequent excellent public support in fighting the *Aedes* mosquito was invaluable in reducing

the incidence of the carrier and in thereby checking the spread of the disease.

Within two months control measures brought the *Aedes* breeding index in Honolulu from 5.7 per hundred premises inspected to a level fluctuating a little over or under 1.0, where it remained as a result of continued control activities.

Sporadic cases of dengue have been reported since the epidemic year, but none have been reported since July, 1945. However, increased speed and frequency of airplane travel between Hawaii and areas to the west where dengue is continuously endemic means an ever-present threat of reintroduction of the disease. Consequently, a continued minimal mosquito control program is being carried on under Territorial funds.

Sudden Deaths of Infants Allegedly Due to Mechanical Suffocation*

JACOB WERNE, M.D., AND IRENE GARROW, M.D.

*Office of the Chief Medical Examiner, City of New York, Borough of Queens;
and the Department of Pathology, St. John's Long Island City and
Flushing Hospitals, Flushing, N. Y.*

THE sudden death of an apparently healthy infant occurs with regularity in every large community. The circumstances surrounding the discovery of the body are frequently such that the laity immediately ascribes the death to smothering. Mattress, or bedclothes, or other crib objects found, or thought to have been found, in contact with the face, are incriminated; and if, as rarely happens today, the infant had been put to bed with another person, overlying of the infant by that person is assumed.

In this country during 1934, 834 such deaths were recorded under List 182 (Accidental Mechanical Suffocation) for infants under 1 year. The number of such cases during 1944, was 1,312, representing an increase of approximately 57 per cent during this 10 year period.¹ In the City of New York, the number of such cases has been said² to exceed those from measles, scarlet fever, and diphtheria combined, and to equal those from whooping cough. In the *Statistical Bulletin*³ of the Metropolitan Life Insurance Company, smothering has been called the greatest hazard encountered during infancy. The fact that one-third to one-half of all fatal accidents during infancy are charged to

this cause has been the subject of editorial comment by both the *Journal of the American Medical Association*^{4a} * and the *New York State Journal of Medicine*.⁵

The Committee on Public Health Relations of the New York Academy of Medicine,⁶ through widely publicized releases in both lay and medical press, has recently outlined specific measures for mothers to follow to prevent these so-called "unnecessary" deaths. This particular campaign was launched after Abramson² called attention to the excessive number of infants under 1 year of age dying from mechanical suffocation in the City of New York. The feeling of culpable negligence experienced by the mother or other person in attendance, and the resultant hostility of family and friends add considerably to the intensity of these tragedies. Since the conclusion that the infant has died as a result of a preventable accident may have serious implications, it should be accepted only after critical examination of the evidence on which it is based.

What is the evidence upon which the certification of death as due to accidental mechanical suffocation is based? It is

* Presented before the Maternal and Child Health Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 11, 1946.

^a The *Journal of the American Medical Association* ^{4b} later gave editorial notice to Davison's ¹¹ work, showing that statistics relating to infant suffocation are misleading in that they err on the side of overestimation.

important to realize that at the present time we have no certain post-mortem criteria for the proof of asphyxial death, apart from finding the means of asphyxiation. For example, the rope in strangulation, and its anatomic effects on the neck. Proof of suffocation by such wilful manual force⁷ which leaves no distinctive mark upon the body may be quite difficult to establish. Since the anatomic effects are not demonstrable, the conclusion that death resulted in this manner must at least be supported by the exclusion of all other causes of death.

During the past fifteen years, the authors have investigated 167 consecutive infants under 1 year of age, found dead in crib, carriage, or bed while in apparent health; belonging to the group which was ordinarily certified as dead of accidental mechanical suffocation.*

In no instance has our investigation proved accidental mechanical suffocation of a healthy infant by bedclothes or in analogous manner.

natural cause of death, therefore excluding suffocation, were the following:

Mastoiditis and otitis media.....	20
Bronchopneumonia and otitis media.....	1
Bronchopneumonia	4
Lobar pneumonia.....	1
Congenital heart disease.....	7
Congenital heart disease and broncho- pneumonia	1
"Idiopathic" cardiac hypertrophy.....	2
"Idiopathic" cardiac hypertrophy and bronchopneumonia	1
Subdural hemorrhage.....	2
Bronchopneumonia and subdural hem- orrhage	1
Meningitis	2
Internal hydrocephalus.....	1

The cases of heart disease were frequently associated with acute respiratory infection.

In the 124 cases showing insufficient gross findings to explain death, comprising 74.3 per cent of our cases under 1 year of age, complete microscopic studies as a rule showed acute inflammation of the respiratory tracts, in association with other significant visceral

Accidental mechanical suffocation	1.2	51.1	0.5

Table 1 indicates that this certification rarely occurs after 1 year of age. In 43 (25.7 per cent) of our 167 cases under 1 year of age in which accidental mechanical suffocation was alleged, the autopsy alone established the presence of fatal disease.

The gross findings in these 43 cases which were adequate to establish a

changes. The lesions encountered have been previously described.⁸ They included tonsillitis, laryngotracheitis, bronchitis, bronchiolitis, interstitial pneumonia, and hemorrhagic bronchopneumonia not grossly detectable. There were lesions frequently in the other organs, including the brain, liver, kidneys, and lymphatic tissues. These lesions were conspicuously absent from the tissues of 31 infants dying of proved violence.*

In all of the 124 cases showing at autopsy insufficient gross findings to ex-

* In the City of New York, all deaths occurring suddenly or unexpectedly, or without medical attendance, or in any unusual manner, or charged to violence, are referred to the Office of the Chief Medical Examiner. During the calendar year 1944 this office investigated 16,155 cases, approximately 25 per cent of the total deaths recorded by the Department of Health. In the Borough of Queens, having a population of over 1½ million, the Medical Examiner's records comprise over two per cent of the deaths annually.

* These cases included 15 of suffocation (most of them infanticide), 6 of drowning, 2 of crushing injuries, 1 of carbon monoxide poisoning, 5 of burns, 1 of ether anesthesia, and 1 of naphtha poisoning.

plain death, the microscopic study indicated fulminating respiratory disease as the best possible explanation for death, with the following exceptions: three cases in which enterocolitis (one due to salmonella) associated with pneumonitis appeared to be the primary cause of death; 4 cases in which dermatitis was associated with pneumonitis; 1 case in which post-vaccinal encephalitis was the cause of death; 1 case in which, in addition to evidence of respiratory disease, recent immunization may have been a factor in causing death by delayed anaphylatic shock, and 6 cases in which no conclusion as to a cause of death was reached. In the last group no tissues were available for microscopic study.

Furthermore, we have also investigated 67 other infants who had been observed to die suddenly and unexpectedly, under circumstances in which there could be no possible allegation of smothering. It is noteworthy that in these infants, observed to die suddenly and unexpectedly, therefore not allegedly smothered, acute respiratory disease was the usual cause of death. The same cause of death, that is, acute respiratory disease, was the usual one in the cases under present consideration, in whom smothering is ordinarily alleged.

In 38 infants there were sufficient gross anatomic findings to identify the disease causing death, as follows:

Mastoiditis and otitis media.....	8
"Idiopathic" cardiac hypertrophy and otitis media.....	1
"Idiopathic" cardiac hypertrophy.....	4
Congenital heart disease.....	9
Bronchopneumonia	2
Congenital heart disease and broncho- pneumonia	2
Lobar pneumonia.....	1
Interstitial pneumonitis with bilateral hydrothorax	1
Bilateral adrenal hemorrhage due to meningococcemia	3
Bilateral adrenal hemorrhage in which no organisms were recovered.....	1
Meningitis due to Friedlander's bacillus...	1

Meningitis due to pneumococcus type III..	1
Meningitis due to pneumococcus untyped..	1
Impetigo of new-born.....	1
Hydronephrosis and pyelonephritis.....	1
Intraventricular hemorrhage.....	1

In 29 infants, there were insufficient gross findings to explain death, but completed microscopic study disclosed the same lesions as in the group allegedly smothered and established acute respiratory infection as the primary cause in 22 cases. In two more, this was associated with encephalitis, in one with dermatitis and in two with enterocolitis (one of which was due to *Salmonella enteritidis*). In two other cases no tissues were available for microscopic study and no conclusion was reached as to the cause of death.

The importance of the microscopic examination is too well appreciated by pathologists to require emphasis. It is nevertheless necessary to state that the medicolegal pathologist has even greater need of this essential technique than does his colleague in hospital practice. The latter, by contrast, has the benefit of a full clinical record, frequently containing the results of informative laboratory tests.

It has been our experience that when the microscopic lesions described above occur there is often a history of upper respiratory infection in the deceased infant, or a contact, or both. Not infrequently there is respiratory illness in the entire family at the time of death, or shortly thereafter. Of the 124 infants found dead while in apparent health and showing at autopsy insufficient gross findings to explain death, there was a definite history of symptoms referable to respiratory infection in at least 25, and a questionable history in 6; in 78 cases those in attendance could recall no untoward antecedent signs, and in 16 no reliable information was available.

In 44 cases of this series there was a positive history of contact with one or

more persons known to have been suffering with acute respiratory disease. In 3 instances there was a doubtful history of contact, and in 4 cases contact was denied by those in attendance. In the remainder, the records did not show that inquiry was made concerning this point.

The suddenness of death so stuns the family that attempts to obtain a reliable history on the first visit to the scene are frequently unsuccessful. Those in attendance often recall, at a subsequent interview, signs and symptoms in the deceased and the contacts to which no significance was attached at the time.

In 4 cases, the subject was one of twins. The other twin subsequently developed clinical disease. In 2 instances, this was pertussis. We have encountered cases allegedly suffocated in families in which other children at the time had pertussis, or mumps. In such cases, the histological findings were characteristic of these diseases.

Analysis of the age incidence of the deaths under consideration discloses that they occur infrequently during the first month and after the first year. The majority are seen in the first 6 months (Figure 1). The peak in our experience is reached during the third and fourth months. The mortality tables for List

FIGURE 1.—The incidence (by month) of infants dying of alleged mechanical suffocation while in apparent health, showing at autopsy insufficient gross findings to explain death. 124 cases

182 (Accidental Mechanical Suffocation) (Table 2); the series of 139 cases of "mechanical suffocation" collected by Abramson²; and the incidence of deaths due to acute respiratory disease (Lists No. 104-114 inclusive) for New York City during 1942,⁹ show a similar age incidence (Figure 2).

may be explained by assuming (1) that there is less exposure to infection, (2) that the infant is still protected by maternal antibodies. As these wear off and contact increases, infections take their toll. Freund¹⁰ in 1926, and Baumgartner¹¹ in 1934 showed for rabbits that the formation of antibodies is deficient in

FIGURE 2—Incidence of deaths by month of age in (a) New York City 1942 certified as acute respiratory disease (Lists 104-114): 443 cases. (b) Deaths in New York City 1939-1943 collected by Abramson² certified as due to accidental mechanical suffocation: 139 cases. (c) Present study: 167 cases.

The low incidence during the first month of life is paradoxical if one accepts mechanical suffocation as an explanation for these sudden deaths. It is precisely during this period, when the infant is weakest, that a maximum number of such deaths would be expected.

The relative freedom of the first month of life from this cause of death

very young as compared with adult animals. If antibody production can be taken as a measure of immunity, and if these animal findings are applicable to human beings, an explanation for the observed age incidence may be at hand.

The maximum seasonal incidence in our cases as well as in all those certified as accidental mechanical suffocation is during the winter months. The same

seasonal as well as age incidence will be found for fatalities from known respiratory diseases (Figure 3).

We have so far considered the positive evidence in our own experience for the existence of significant disease as an explanation for sudden unexpected death of apparently healthy infants. We might now inquire into the prevailing attitude of medical examiners and coroners toward this problem. For this purpose, as noted previously, the original records of one of the better organized jurisdictions were examined;

they included during one year 44 certifications of infant deaths as accidental mechanical suffocation (Table 3).

Of the 44 cases, 12 were autopsied and 32 were not. Of those autopsied, the brain was described in only 10; the neck organs in 7; the middle ears and mastoids, in none. Microscopic examination was recorded in only one single instance. This was described as "negative." There was no record of such examination in the remaining 43 cases. Thus, not only was there failure to perform autopsies, but failure to

make microscopic studies. Besides these deficiencies, there was another source of error. In 3 cases, the autopsy protocol indicated a different cause of death: laryngotracheitis, or bronchopneumonia, or congenital heart disease. Yet these cases had been certified as accidental mechanical suffocation.

Since in 25.7 per cent of our cases gross autopsy findings immediately excluded death by accidental mechanical suffocation, all such certifications without autopsy may be considered inaccurate. Furthermore, we may consider as unsatisfactory all autopsies in which there was failure to examine the brain, the mastoids, the middle ears, and the neck organs, in addition to the routine dissection of the thoracic and abdominal viscera. We may also disregard all cases that have not had a complete microscopic examination.

The experience of Davison¹² (Figure 4), Coroner of Birmingham, England, is of interest in this regard. From 1918 to 1924, 130 instances, about 21 cases per year, of accidental mechanical suffocation were recorded. From 1938 to 1944, the number of cases dropped to 18, or about 3 per year. Since during the earlier period the population was about 550,000, and during the later period, about one million, the actual

drop was from 21 to 1½ per year, in relation to the total population. Davison states that autopsies became routine in these cases only after 1926. The lag in the drop between 1926, when autopsies were instituted, and 1938, when the incidence of this certification became low, can be explained by the interval that may elapse between the realization of the problem, and the acquisition of sufficient pathological experience to find the lesions and assess their significance. We admit that several years elapsed before such diagnoses as accidental mechanical suffocation, and status thymicolymphaticus* disappeared from our own records.

Tables 4 and 5 show the incidence of these certifications in the country at large, in several states, and in New York City. The extreme variability in the occurrence of List 67 and 182 can only be explained by assuming that the criteria for these diagnoses are most indefinite. By contrast, the incidence of such standard causes of death as lobar pneumonia, for which clinical and

*The best opinion in this regard has been aptly expressed by Holt and McIntosh.¹³ "Status lymphaticus is no longer regarded as an explanation of sudden death. It is now recognized that infants and children who die suddenly from any cause exhibit a relative enlargement of the thymus and other lymphoid structures, which is merely an expression of good nutrition."

pathological evidence is easily obtained, shows no such bizarre characteristics. It is noteworthy that drowning, an accidental cause, maintained a consistent level in the Boroughs of New York City over the years (Figures 5 and 6).

Although the evidence we have assembled indicates that accidental mechanical suffocation is hardly an acceptable explanation for sudden death during infancy, nevertheless such certifications have increased considerably during recent years. An explanation for this increase may be found in our mortality tables under Lists 67 and 200,

diseases of the thymus gland (mainly status thymicolymphaticus) and ill-defined or undetermined causes of death respectively. It may be noted that the increase in certifications under List 182 reflects the decrease seen in those under 67 and 200 (Table 5).

We have shown (1) that there is no anatomic evidence for asphyxial death as such,¹⁴ (2) that in the cases allegedly dying of accidental mechanical suffocation, the pathological investigation established another cause of death as a rule. Upon what evidence then are certifications of accidental mechanical suffocation ordinarily made? We be-

FIGURE 6

lieve that they are based on a misinterpretation by the layman. This misinterpretation receives endorsement from the medical examiner or coroner who stops his investigation at the scene of death. We do not wish to minimize the significance of the visit to the scene. In certain cases this may be the most important element of the medicolegal investigation. However, it is never sufficient in itself, and its value must be measured in terms of the reliability of the information it provides. When an adult is unexpectedly found dead, the body is usually undisturbed before the arrival of the medical examiner or coroner. The same situation does not obtain in the case of infants. When first discovered, though it may be suspected that the infant is in a critical condition or even dead, attempts at resuscitation are usual. In the resultant confusion, the position of the body at death is changed. It can seldom be accurately reconstructed. However, assuming that most of these cases

actually are found with face down or face covered, as reported, the mothers usually state that it was the infant's habit to sleep in the prone position. It is common knowledge that infants often prefer this position. Bedclothes or blankets so often described as completely covering the face were never, in our experience, judged to have been so closely applied as to prevent all access of air. We agree with Archibald¹⁵ that the well baby will resist all attempts at suffocation. In experimental animals, attempts at suffocation result in violent struggling. The struggling movement of babies provoked by any impediment to breathing would probably dislodge the amount of bedclothes ordinarily incriminated.

Although important from the medical and public health standpoint, the accurate certification of these deaths possesses another aspect of practical significance. If they are due to suffocation, then Abramson's² advice should be followed by mothers: that is, infants

should never be permitted to assume the prone position unless constantly guarded. On firmer ground, in our judgment, rests the suggestion of Adams¹⁶ that by placing the infant in this position, postural drainage of infected secretions from the tracheobronchial tree may lessen the likelihood of pneumonia.

The conception that fulminating infections are responsible for sudden unexpected death is not a new one. Farber¹⁷ cites a case in which Wolbach, at the turn of the century, diagnosed meningitis by microscopic examination in a case previously certified as dying of status thymicolymphaticus. Farber,¹⁷ and Goldbloom and Wigglesworth¹⁸ have described instances of sudden unexpected death during infancy associated with fulminating respiratory infection.

Sudden death is rare in infants, and still more rare in adults who are apparently healthy or are suffering from "minor" diseases. When it occurs while the infant is being observed during the fatal collapse, or is found dead with suffocation excluded by the circumstances at the scene, microscopic lesions can almost always be seen, as our series of medicolegal cases shows. These microscopic changes correspond with those found in fulminating diseases, mostly respiratory infections. We found the same type of microscopic lesions in infants allegedly dead of accidental suffocation.*

The significance of such microscopic lesions may be obscured by the presence of advanced gross pathological changes that occur in infants, children, and adults who are hospitalized because they suffer from frank pneumonia, meningitis, or other diseases. The pathologist who studies hospitalized patients usually looks for and usually finds in his material the anatomical changes characteristic for the specific disease. Fur-

thermore, the source of material for the pathological study of sudden death is very limited in hospital pathological laboratories as compared with the source of material of the medicolegal pathologist who investigates sudden death in a large population.

The medical examiner sees far more cases in which sudden death is unassociated with fully developed disease in the conventional sense. Since in many of his cases microscopic changes may be the only features of a fatal disease, attention must be focused upon these microscopic changes if they are to be discovered. An objection that might be raised in this regard is well disposed of by Burke-Gaffney¹⁹:

Even microscopic lesions may be the only features accountable for death. It will be said that microscopic lesions will rarely occur without manifesting themselves macroscopically as well. Were this true, their very rarity would in itself be a particular reason for keeping them in mind, but in fact they can and do occur as the sole evidence of morbidity in a surprisingly large number of cases. That they are easily missed is to be explained by the very excellent and somewhat obvious reason that they are microscopic. The presence of such lesions playing an unsuspected but essential part in medicolegal practice I will not endeavor to illustrate by means of examples taken from my own cases

The histological lesions which we have encountered in the cases under present discussion reflect associated physiological disturbances which may be regarded as the best available explanation for such deaths. There seems to be an apparent discrepancy between the extent of pathological changes and the fatal outcome, in infants found dead while in apparent health. In this connection consideration should be given to the following point: Death in many infectious diseases is preceded by and is probably the result of medical shock. The factors which bring about circulatory collapse or medical shock have not been exactly determined; there is no exact relationship between severity

* In 6 of the earliest cases, as stated previously, sections were not available for study and therefore such cases are classified as of undetermined cause of death.

of clinical or gross anatomical changes in infectious diseases and the probability of shock and death, or recovery. The clinical improvement of a patient just after the crisis of lobar pneumonia is dramatic; but the x-ray examination still shows massive involvement of the lung. It is well known that gross morphological changes do not necessarily reflect the prognosis of a disease. Patients with pneumonia involving both lungs may recover; and others with involvement of one lobe may die. In some who die, only a small patch of consolidation may be demonstrable grossly or, as in the case of the infants under discussion, the involvement may be microscopic.

The susceptibility of infants to trauma is well known. An extent of skin burn or crushing injury from which an adult might easily recover has been repeatedly known to cause death during infancy. Diarrhea may cause death in infants although the clinical course may seem mild and the anatomical findings in the intestines be limited to slight congestion. Kahn²⁰ found that adult rabbits react vigorously at the site of intracutaneous injection of hemolytic streptococcus but do not die; whereas very young rabbits hardly develop a local inflammatory reaction and die with bacteremia. This observation confirmed that of Freund²¹ who used pneumococci in a similar experiment.

We have found morphological evidence of systemic involvement in apparently mild upper respiratory infections.²² The "bronchitis" which might easily be weathered by the average adult may in susceptible infants prove to be a fatal system disease.

Under the title of pulmonary congestion, Brouardel²³ in 1896 stressed the importance of "bronchitis" (also known as capillary bronchitis) as a cause of sudden death during infancy:

Another common cause of sudden death, in children 2 or 3 months old, is bronchitis.

Bronchitis is one of the most dangerous diseases to which children are liable; the child cannot cough; it does not know how to expectorate, or how to free itself from the obstruction to its breathing; part of the respiratory area thus becomes useless, and the lesions just described, of atelectatic portions of the lungs, are found post-mortem; it is Laennec's "suffocating catarrh." Bronchitis is probably the explanation of many cases of so-called "overlying"; laryngismus stridulus will account for many more; but still in some, as in the following one, death is simply the result of accidental smothering; the child being placed to sleep in a large bed, and slipping down beneath the bedclothes, or turning face downwards on a large soft pillow.

With all except the last part of this statement of Brouardel,²³ we are in complete agreement. We would prefer to consider his occasional case that "slipped down beneath the bedclothes or turned face downwards on a large soft pillow" as part of an expected percentage in which, by all the means available to competent hands, in the light of existing knowledge, no cause of death may be demonstrable.

Especially in our early cases, we have encountered deaths for which the cause still remains undetermined. Their number has diminished with increasing experience and more extensive pathological study. The proper approach to this problem, however, requires that failure to find a cause of death be readily admitted and honestly recorded; and not concealed under such listing of our mortality tables as accidental mechanical suffocation and status thymicolymphaticus.

SUMMARY AND CONCLUSIONS

List No. 182, accidental mechanical suffocation (of the *International List of Causes of Death*), is erroneous. There were 1,312 such cases under 1 year of age, certified throughout the United States during 1944, an increase of approximately 57 per cent over the previous decade.

In 167 consecutive cases of infants allegedly suffocated in crib, carriage or bed, 74.3 per cent of whom showed at autopsy insufficient gross findings to explain death, microscopic study revealed fulminating respiratory disease in the great majority of instances. The significance of these findings was further confirmed by their absence in actually healthy infants dying of proved violence and their presence in infants observed to die suddenly and unexpectedly of proved respiratory infection.

Efforts to prevent sudden death of infants should be directed toward diminishing exposure to known sources of infection during this highly vulnerable period of the infant's life; and to the education of parents in the early signs of acute respiratory disease and their significance. It is further suggested that the American Public Health Association appoint a commission consisting of pediatricians, pathologists, and health officers for the comprehensive study of this important problem of sudden death during infancy.

Appraisal of Nutritional Status

Including Some Recent Observations on Iron and *Lactobacillus casei* Factor (Vitamin M, Folic Acid) * †

WILLIAM J. DARBY, M.D., PH.D.

*Departments of Medicine and Biochemistry, Vanderbilt University
School of Medicine, Nashville, Tenn.*

NUTRITION surveys such as those which have been made in Tennessee¹ and North Carolina² have consisted of dietary studies, laboratory assessments of nutritional status, and careful physical examinations for signs of nutritional deficiencies. These surveys were made in part to provide a basis for action by public health administrative bodies. The data from the surveys have not always supported preconceived notions of the problems in the area, and analysis of the data has led to the serious questioning of the validity of some widely employed criteria of deficiencies. A study of the data from surveys and other sources has led to the suggested definitions of various zones of nutriture from clinically manifest deficiency disease to zone of saturation and to the conclusion that the clinical definition of physical normality, i.e., the state of one who is well and not handicapped by some disturbances manifested by symptoms,³ may be the most useful one for the application to nutrition work.⁴

Epidemiologic approaches to nutritional problems have been most fruitful

in the past; as examples one may recall the study of the relationship between iodine deficiency and goiter, fluorine and dental health, diet and beriberi, xerophthalmia and vitamin A, or consumption of corn and pellagra. In all of these now classic studies correlations were obtained between food intake and disease conditions. Similar approaches should continue to be fruitful if health impairments in the population are due to malnutrition. The failure to find correlations between measurements of intake and the evidences of health performances may be taken to indicate that: (1) no relationship exists between the two variants, or (2) a third variant exists which obscures the relationship between these two tested. It has been stated⁵ that the third factor thus obscuring some correlations is time, i.e., that lack of correlation is due to changes in dietary habits since the development of the physical stigma. If so, one might reasonably regard such stigmata as scars and, therefore, not manifestations of *currently existing* deficiencies. However, others^{4, 2b, d, c, 7} have felt that the frequently noted lack of correlations between measures of intake and occurrence of physical findings was more likely due to the non-specificity of the clinical findings. There is no doubt that various physical signs of deficiencies may be met with in the general population, but reasoning that the appearance of these

* Presented at the Joint Meeting of the Food Industries Advisory Committee and the Scientific Advisory Committee of the Nutrition Foundation, Inc., Washington, D. C., April 5, 1946.

† The studies from Vanderbilt University upon which much of this paper is based were made possible in part by grants from the Nutrition Foundation, Inc., the International Health Division of The Rockefeller Foundation, and the Tennessee Department of Public Health.

abnormalities is always due to a simple dietary deficiency and that the incidence of a sign, in absence of supporting data, is a measure of a given dietary deficiency is illogical. The exploration of the reason for lack of expected correlations may be enlightening and provide a sounder basis for the interpretation to public health administrators of the nature of nutritional defects which deserve correction.

These points may be illustrated by the following findings from our surveys and clinic: In a survey in a rural county in North Carolina^{2c, d} in 1943-1944 there was found to be no difference in the incidence of corneal vascularization or dilation of the limbic plexus (signs often employed as indicators of riboflavin deficiency), between those groups of persons recording a daily intake of 1.35 mg. or more of riboflavin and those obtaining less than this amount. In the group of 25 white persons exhibiting angular fissures and/or tongue changes resembling those seen in riboflavin deficiency, only 4 individuals failed to present some obvious cause of the lesions other than ariboflavinosis, and but 1 of these 4 had a daily intake of less than 0.7 mg. of riboflavin. It was concluded that ariboflavinosis was not a serious problem in this region. It was noted, however, that certain of the persons with lingual changes and reasonably adequate dietary intakes of riboflavin also had a definite anemia. Furthermore, the glossitis, cheilosis and anemia, but not the corneal invasion, of one of the subjects responded promptly to the administration of iron and riboflavin.⁸

This observation, coupled with the finding of Waldenström,⁹ that the oral lesions of Plummer-Vinson syndrome¹⁰ respond to therapy with iron alone, led to a detailed study of patients exhibiting such oral lesions. It has now been demonstrated⁸ that angular fissures and superficial glossitis may accompany

chronic iron deficiency anemia of mild degree; that subjects with this combination of findings were deficient in iron was proved by use of radioactive iron absorption studies as developed by Dr. P. F. Hahn and his coworkers.¹¹ Finally, it was demonstrated that in these cases the oral lesions do not respond to vitamin B-complex therapy but that they heal rapidly when the patient is given iron. The lack of response of these lingual changes to therapy with niacin and riboflavin and their subsequent prompt remission after administration of iron is illustrated by the following case report:

M. B., 40 year old colored woman, complained of a sore mouth and tongue and burning of the throat upon swallowing. The symptoms were of 2 months' duration. There had been increased nervousness and easy fatigability for the past year or so. Profuse menstrual bleeding for a 3 week period had occurred 3 years previously and the menstrual periods recently had been 3 weeks apart. History indicated a satisfactory food intake except that meat was eaten infrequently and milk was included only every second day. Examination revealed a tongue with patchy denudation of the papillary tufts, atrophy of the filiform papillae and a glistening surface with some pigmented areas on the left (Figure 1). Except for small uterine fibroids the remainder of the physical examination was non-contributory. Laboratory studies revealed 4.41 million erythrocytes per cu. mm., 10.0 gm. of hemoglobin per 100 ml., and a packed cell volume of 32 per cent. There were 20° of free hydrochloric acid on gastric analysis following histamine stimulation. The symptoms and laboratory findings were unaltered by therapy with 3 mg. riboflavin, 75 mg. niacin, and 9 mg. of thiamine daily for a period of 7 weeks. Therapy was then instituted with ferrous sulfate, 0.3 gm. three times a day. Two weeks later the symptoms of glossitis and the sensitivity of the throat had disappeared and the patient felt less nervous. There was complete regeneration of the lingual papillae and the dorsum of the tongue was covered with the normal papillary tufts (Figure 2). The hemoglobin concentration had risen to 12.0 gm. With continuation of the iron therapy improvement continued, and after 6 weeks of therapy the laboratory findings were: hemoglobin, 12.8 gm.; erythrocyte count, 4.52 million; and packed cell volume, 42 per cent.

FIGURE 1—Tongue of patient M.B. showing denuded surface, atrophy of filiform papillae and visible pigmentation on the side.

In our clinic patients with these oral lesions are more frequently found to be deficient in iron than in B vitamins. Certainly not all patients deficient in iron exhibit these lesions, and there is no question but that such oral lesions are sometimes signs of B-complex deficiency.

With this background there has been tabulated from three nutrition surveys (two in Tennessee^{11, 12} and one in North Carolina²⁰) the data on incidence of glossitis and/or cheilosis by level of hemoglobin (Table 1). Because of the recognized relationship of adentia and cheilosis¹³ the edentulous persons were excluded from the tabulation of the North Carolina data. With full recognition of the small numbers involved in this group, the trend in all of these studies appears to warrant further consideration of iron deficiency as a cause of some of the angular fissures and the glossitis encountered in the surveys of the general population. There are multiple causes of these lesions, one of which is iron deficiency. Obviously, these lesions are nonspecific and the incidence of them alone cannot be used

to estimate the incidence of riboflavin deficiency. Likewise, the presence of the lesions could not be used as a sole measure of iron deficiency within a population.

This example serves to illustrate that epidemiological studies of nutritional problems can be of value in understanding the milder manifestations of deficiencies, provided one adopts a tangible criterion and does not attribute absence of correlations merely to recent changes in dietary intakes.

One word should be said regarding the nature of iron deficiency in adults. This deficiency occurs more commonly in women.¹⁴ It is not of dietary origin, but is due to the conditioning effect of excessive blood loss.¹⁴ Large stores of iron cannot be built up in the body by increasing dietary intakes to protect against such emergencies because the intestinal wall absorbs iron only as the element is required,¹⁵ the dietary excess remains unabsorbed. Because of the quantities involved, effective therapy of

iron deficiency requires therapeutic doses of iron, not merely iron-rich diets.^{14, 16} The problem, then, is one of education of physicians and of women as to when iron deficiency should be suspected. The solution of the problem is not by increasing generally the iron intakes of the healthy members of the population.

In collaboration with Dr. P. F. Hahn and others¹⁷ we have extended our study of iron to an investigation of groups of school children in Nashville, Tenn. In two areas representing the two extremes of the economic scale we have employed for the first time on a mass scale the radioactive iron absorption technic. The findings indicate that iron was not a limiting factor in the hemoglobin levels of these groups of school children age 7-10 years. The mean hemoglobin levels of the children were approximately 13.0 gm. per 100 ml. and the calculated total daily intakes of iron averaged about 11.0 mg., an intake which has been found to be satisfactory by other investigators.¹⁸ This mean hemoglobin level may be considered satisfactory since it is similar to that observed for healthy children in

many other sections of the world,^{2f, 25} some of whom were known to be abundantly nourished.^{25b} It seems that the arbitrary choice of levels of from 10 to 14 gm. as anemia levels for young children indicative of iron deficiency¹⁹ is not justified. Certainly, hemoglobin levels of 13.5 gm. in children cannot be taken to indicate dietary inadequacy of iron as has sometimes been assumed.²⁰

Another recent discovery which may influence the interpretation of nutrition surveys is the demonstration²¹ that the deficiency disease, sprue, is relieved by a newly synthesized vitamin variously designated as vitamin M, *Lactobacillus casei* factor, "folic acid," vitamin B₁₂, etc. Sprue is a disease characterized by diarrhea with increased fat content of the stools, glossitis, macrocytic anemia, moderate leukopenia, pigmentation of the skin, impairment of gastrointestinal absorption as indicated by a flat oral glucose tolerance curve, a flat vitamin A tolerance curve, a very low serum carotene, a characteristic gastrointestinal pattern on x-ray examination, and striking loss of body weight. Bone marrow studies reveal a maturation arrest in

the megaloblastic phase—a finding similar to that seen in pernicious anemia, nutritional macrocytic anemia, tropical macrocytic anemia, macrocytic anemia of pregnancy, and some other syndromes. The disease is more common in tropical regions, but it occurs endemically in the United States, cases having been reported from many sections of the country. It has long been considered that the disease in non-tropical and in tropical areas is identical and, hence, the entity should not be classified as “tropical” and “non-tropical.”²²

Because of the similarity of the clinical picture of sprue in man and vitamin M deficiency in the monkey, the demonstration by Day and his coworkers²³ that a purified preparation of *L. casei* factor exhibited vitamin M activity for the monkey, led us to postulate that this vitamin might be efficacious in sprue. In November, 1945, we reported the response of the first cases of sprue to the new synthetic vitamin.*^{21a} This finding was rapidly confirmed and extended.^{21b, c, d} We have treated 4 cases of the disease to date and all have shown unmistakable clinical and hematologic response to the synthetic vitamin in doses of 15 to 20 mg. daily. The symptoms of glossitis have disappeared within 3 or 4 days and a rapid regeneration of the lingual papillae has occurred; simultaneously there has been an improved general sense of well-being: the diarrhea has subsided; the appetite has increased to the point of becoming insatiable; and impressive weight gains have followed. One man gained 43 lbs. in 3 months, one woman gained 22½ lbs. within 29 days.

The prompt hematologic response which occurs has been depicted in detail in a previous report.^{21b} Increases in all of the formed elements in the blood have been seen and the bone marrow

rapidly loses its primitive character. The platelets have risen from pre-treatment levels of 200,000 or so to post-treatment peaks of 2 to 4 million per cu. mm.

The studies in these patients indicate that this vitamin is concerned with maintaining the normal absorption of the gastrointestinal tract. We noted a return toward normal of the glucose tolerance curves of our patients within a few days after *L. casei* factor was given.^{21b} The prompt cessation of the diarrhea, the remarkable weight gains, and the later occurring rise in serum carotene and change in vitamin A tolerance curve²⁴ all speak for improvement in gastrointestinal absorption by this factor. The effect on appetite is so striking that it is difficult to believe other than that it is a specific result of the therapy. Finally, there is in some cases a decrease in the fecal fat loss expressed in per cent of dry weight of the feces, but a more dramatic decrease in total fat loss due to the decreased quantity of stool. Repeated x-ray examinations of the gastrointestinal tract have not yet permitted a definite conclusion as to the ultimate effect of the vitamin on the “deficiency pattern” which is observed in sprue.

These results indicate that all of the cardinal manifestations of sprue which ordinarily respond to liver extracts respond to this vitamin. That this is but one of a number of active factors in the vitamin M-complex may be surmised from existing evidence. Although the exact pathogenesis of sprue is not clear, it is obvious that at least one number of the vitamin M group, i.e., *L. casei* factor, corrects a deficiency which may exist in man, and it can be assumed that members of this group of substances are required by the human being.

Many questions arise as a result of these studies: Which members of the vitamin group chemically related to *L. casei* factor are effective in man? Is

*The synthetic *L. casei* factor employed in our studies was kindly supplied by Dr. Stanton M. Hardy, Medical Director, the Lederle Laboratories, Inc.

sprue a simple dietary deficiency? What is the human requirement of *L. casei* factor? Do there exist various degrees of vitamin M deficiency within the population? How does this discovery affect our interpretation of the oral manifestations of deficiency states, of the hematologic findings from nutritional surveys, of the gastrointestinal symptoms and findings which are frequently recorded in nutrition surveys? What is the importance of dietary *L. casei* factor as contrasted to that synthesized by the intestinal flora? Will studies with this new vitamin clarify our understanding of the relationship of sprue, pernicious anemia, nutritional macrocytic anemia, macrocytic anemia of pregnancy, and perhaps pellagra? What precautions should be taken in food processing to avoid destruction of this vitamin? Answers to these questions cannot be provided at this time. It is to be hoped that critical tests will be made of the points raised regarding this vitamin before our enthusiasm for the importance of the dietary supply of this latest factor to be added to those food essentials for man gets ahead of our positive knowledge.

CONCLUSION

In conclusion, it is hoped that this discussion has illustrated: (1) that the maintenance of a critical view toward epidemiologic studies in nutrition can, if properly followed, lead to a better understanding of the existing problems in the population, (2) that continued restudy of survey data and revision of our interpretation of such data are necessary in order that we follow sound nutrition practice in designing our public health programs.

Are Frozen Foods a Public Health Problem?*

GERALD A. FITZGERALD

Director, Frozen Food Foundation, Inc., Syracuse, N. Y.

AS we become better acquainted with the history of peoples of frigid areas, we learn that food preservation by freezing has been practised perhaps for thousands of years through natural climatic action. Creating refrigeration by artificial means in warmer climates, however, is a comparatively recent development.

Starting with Dr. William Cullen in Scotland in 1820, who invented a sulfuric acid refrigerating apparatus for cooling biologicals, advances in mechanical refrigeration were slow. Salt and ice freezing mixtures were satisfactory only for local uses. Linde in Germany, in the middle 1800's made the first practical contribution with the introduction of the expanded air machine. Milwaukee became the center of the beer industry largely because Vilter made his ammonia refrigerating machines there. Fish was frozen commercially with mechanical refrigeration, using ammonia in 1891 at Sandusky, Ohio. Although this was the first commercial venture using mechanical refrigeration, it was preceded by ice and salt freezing of fish in 1861, poultry in 1865, and meats in 1880. Frozen fruits were introduced in 1905, vegetables in 1930, precooked entrees in 1942, and bakery products about a year later.

THE FLORA OF FROZEN FOODS

Sanderson and Fitzgerald¹ presented a paper at the Third International Congress of Microbiology in 1939, "The Bacteriological Flora During Spoilage of Frozen Vegetables," which was never published in full. The facts are herewith presented because this information should receive wider notice and because no similar studies of this nature have since appeared. They confirmed the work of others that the usual flora of frozen vegetables consisted of members of the genera: *Achromobacter*, *Aerobacter*, *Bacillus*, *Chromobacterium*, *Flavobacterium*, *Lactobacillus*, *Micrococcus*, *Phytomonas*, *Pseudomonas*, *Sarcina* and *Serratia*. The above organisms had usually been isolated from frozen or freshly defrosted and not from spoiled frozen foods. The study of the latter presents quite a different picture.

Prescott and Geer² had suggested inoculating frozen foods with an acid-forming organism as a safety factor to produce acid and thus spoil the product through souring before the toxigenic types could produce an enterotoxin. Berry (1933)³ had discovered that after seven days at room temperature, frozen peas yielded *Lactobacilli* as the predominant organism.

In the Sanderson-Fitzgerald study, spoilage at 10, 21, and 32° C. was investigated. Ten gram samples were taken and all were incubated at 25° C. for 72 hours. The earlier stages of de-

* Presented before the Food and Nutrition Section of the American Public Health Association, at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 14, 1946.

composition disclosed an unexpected rise in pH in which the decomposition products had a somewhat sulfuretted (H₂S) quality. However, at 21° and 32° C., a sudden drop in pH usually occurred during spoilage in 11 to 13 hours.

In the soured products, only *Flavobacterium* and *Micrococcus* predominated repeatedly. Yet experience indicated that neither of these types was capable of producing acid in such quantities or so rapidly as was occurring in the samples of corn, peas, and spinach being investigated. It was quite evident that the Bacto-nutrient agar being used was not a satisfactory medium for such a study.

With the thought that streptococci might be implicated, a streptococcus medium of Pabulum infusion agar was tried. Immediately, counts increased tenfold. Using special streptococcus media, streptococci were consistently found to be the cause of souring asparagus, peas, wax and green beans, and corn which had been frozen in factories located in widely scattered parts of the United States. The remainder of the investigation consisted of an attempt to identify the causative organism. Dr. C. P. Hegarty of Oregon State College and Dr. B. E. Proctor of Massachusetts Institute of Technology cooperated in the identification studies.

The consensus was that one and possibly two strains of *Streptococcus faecalis* were responsible. Moreover, an attempt

to discover the source led to the fact that the same organism could be removed aseptically from within the seed coats of peas and kernels of corn. Thus, the apparent connection between the acid producing organism described and the *Enterococci* is difficult to explain.

The rapid souring of frozen vegetables may be nature's way of protecting the frozen-foods-eating public. It is hoped that similar work will be undertaken by others because of uncertainty with respect to the causative organism. For the purpose of assisting others to continue this work, Chart 1 is presented to show the biochemical differentiation of two strains of an organism presumed to be *Streptococcus faecalis* as determined in the above mentioned investigation. It should be noted that several of the streptococcus strains isolated differed in certain characteristics. The majority of the cultures failed to ferment lactose even after 2 weeks' incubation. One group failed to grow at 10° C.

In summarizing the work reported, it is evident that the bacteriological flora of frozen foods is very extensive, but of great significance is the apparent presence of certain very active acid producing types so that toxigenic or pathogenic types may be entirely inhibited during the spoilage process. This presumption remains to be unequivocally proved. As yet, therefore, one cannot avoid consideration of the implications of *Clostridium botulinum*,

CHART 1

BIOCHEMICAL DIFFERENTIATION OF TWO STRAINS OF *Streptococcus faecalis*

	H ₂ S	Growth in Presence of										Acid Produced from									
		0° C.	15° C.	30° C.	5% NaCl	pH 2.0	0.5% Meth. Blue	Strong Reduction	Survived 60° C., 30 min.	NH ₃ from Peptone	Starch Hydrolyzed	Gelatin Liquefied	Glucose	Sucrose	Lactose	Maltose	Trehalose	Mannitol	Inulin	Sorbitol	Salicin
1	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+

* Strain 2 did grow at 10° C. after two weeks.

† In strain 2, cultures only three have shown acid production at two weeks.

Staphylococcus aureus, the Enterococci and Salmonella and other pathogenic types which may contaminate frozen foods.

EPIDEMIOLOGY OF FROZEN FOODS

From the start, public health minded food technologists worried about the implications of botulism, *Staphylococcus* food poisoning, and pathogenic manifestations resulting from the unregulated production and use of frozen foods. As yet, such fears have not materialized in spite of the fact that one or another of these foods has been marketed commercially in ever-increasing amounts from sources in every section of the country for many years.

Large-scale output of frozen meats, in effect, dates from the publication in 1898 of a report⁴ by the British Society of Public Analysts giving that product a good nutritional rating. The meat industry has been very careful in freezing meat, and consequently it has caused no health problems either in the United States or abroad.

Despite rather extensive shipments of frozen fish, only one reference has been found on sickness caused specifically by this product. Unfrozen shellfish have long been recognized as potential health hazards.

Epidemiology of frozen desserts has received much study. Without doubt, the control experience gained by investigators in this field will be of great significance in establishing sanitary measures for the newer phases of the frozen food industry, particularly frozen precooked products. It is significant that the American Public Health Association has taken the lead in proposing tentative methods⁵ for the microbiological examination of frozen foods.

Frozen strawberries have been marketed for soda fountain purposes since 1905. It was early found that their high acidity was responsible for the

sterilizing action which occurs during long-term freezing storage.

Frozen vegetables, however, have been generally regarded as potential public health hazards because of their practically neutral state. As a result, several serious studies were made during the early '30's.

Prescott and Geer² dispelled fear of botulism from frozen vegetables in work which was published in 1936. Their studies, as well as those of Meyer, Tanner, James, and others, indicated that spores of *Clostridium botulinum* resisted freezing, but no toxin was produced at refrigerator temperatures after defrosting for several days, and that there was little or no danger of botulism from frozen foods which were properly handled. However, they have implied that when improperly handled either in plant or kitchen, frozen vegetables may cause trouble.

Jones and Lockhead,⁶ Dack,⁷ and others who have studied *Staphylococcus* food poisoning extensively imply that frozen cooked foods and bakery products might contain public health hazards based on the epidemiology of their unfrozen counterparts. While many investigators now may be investigating such possibilities, the literature contains hardly a case of authenticated food poisoning directly caused by bacterially contaminated frozen foods prepared commercially for sale to the retail and institutional trades. Despite this, evidence may be accumulating to change the situation. It is important, therefore, to study the bacteriological picture thus far presented in the literature.

BOTULISM INVESTIGATIONS

Dack⁷ says that botulism is a disease due to an enterotoxin formed by the growth of botulinum microorganisms which, after the symptoms appear, has produced physical damage often resistant to specific antitoxin therapy.

In the early days of the canning in-

dustry botulism was a serious obstacle to the growth of the industry. One laboratory has spent 26 years on this project which is not yet finished. Accordingly, there is no longer any fear of botulism from foods *commercially* canned in tin or glass because of safety factors used. Nevertheless only during the recent world war was the botulinum enterotoxin isolated and identified. Being a protein, giving the usual protein reactions, its identification has not yet proved of specific practical value.

Although *commercially* canned foods are no longer implicated in botulism outbreaks, home canned foods are continually causing sickness and death even though federal and state governments have spent millions in educating the public about home canning methods. It may be that conversion from home canning to home freezing may automatically eliminate botulism as a grave public health hazard.

The previously described work of Prescott and Geer,² Tanner,⁸ Meyer, and others has given experienced investigators confidence that frozen foods do not present any more serious botulinum, food poisoning problems than do fresh foods. Dr. K. F. Meyer probably expressed the group thinking in this recent statement to the writer: "My epidemiological experience with frozen foods indicates that frozen fruits and vegetables do not constitute a health hazard in so far as botulism is concerned."

STAPHYLOCOCCUS FOOD POISONING INVESTIGATIONS

Work with human beings and animals shows that various subjects, and even the same subject at different times, react differently to the same dose of the enterotoxin. Accordingly, the only sound evidence that frozen foods can be the source of *Staphylococcus* food poisoning would be actual epidemics unequivocally proved to be caused by such foods.

Jones and Lockhead⁹ found that of

fifty strains of *Micrococci* isolated from frozen vegetables, twelve were able to produce an enterotoxic substance. They also found that of eighteen strains of *Staphylococci* capable of elaborating enterotoxic substance in pure culture in semi-solid starch medium, only eight were able to produce this in frozen corn defrosted 24 hours at room temperature (20° C.); but these eight were unable to produce enterotoxin in a refrigerator at 4.4° to 10° C., where no multiplication of *Staphylococci* was observed. Segalove and Dack⁹ conducted temperature incubation studies and found that below 4.0° C. (40.1° F.) the toxin was not formed after 4 weeks' incubation. Monkeys were used in these tests.

McCastline, Thompson, and Isaacs¹⁰ describe an outbreak of *Staphylococcus* food poisoning due to ice cream custard. Tanner⁸ describes an outbreak which was traced to frozen fish. Rumors of outbreaks in Army and Navy camps from frozen eggs and other products are not well authenticated.

Considerable additional evidence is needed to support a case for or against *Staphylococcus* food poisoning from frozen foods. The first attempt to get down to fundamentals is the proposal of a committee, composed of leaders of various types of food trade organizations, to set up a fund with which to conduct basic studies in *Staphylococcus* food poisoning. Even though frozen foods are not definitely major offenders, the frozen food industry has every reason to cooperate in such studies to the fullest extent.

Frozen precooked foods such as chicken a la king may potentially be sources of *Staphylococcus* food poisoning. One can easily visualize the contamination which may take place in hand-picking poultry meat from cooked chicken. One can also visualize the difficulty of sterilizing such meat without re-cooking. A person having a boil or other festering sore, or a cold or other

similar infection, might cause the contamination, since toxigenic *Staphylococci* may be present. When such highly contaminated meat is combined with starch, milk, or egg-thickened cream sauce and frozen it is quite impossible to avoid the resulting bacteriological contamination no matter how careful, clean, or well regulated the operation may be otherwise. Spoilage of such a product at room temperature would probably be necessary to cause sickness, however, because Lockhead and Jones⁶ indicated the toxin cannot be elaborated while the food is refrigerated.

Our knowledge of the *Staphylococcus enterotoxin* indicates that it is heat-stable, and will withstand boiling for 10 minutes. If present in a product it is certain to cause trouble. Fortunately, it is not so fatal a toxin as that which causes botulism, but it is serious enough to warrant the costly research which its study, control, and prevention will require.

The fact that frozen precooked entrées and baked goods are usually reheated before serving presents an excellent opportunity to sterilize these products. Gilcreas and Coleman¹¹ determined that *Staphylococci* in custard filling are rendered non-viable in 15 minutes at 430° F., and in 20 minutes at 420° F. It is estimated that such treatment should free the material of toxigenic organisms.

Cathcart and Merz¹² discovered that the presence of chocolate and cocoa inhibited enterotoxin production in the absence of eggs. They also advocate boiling the custard¹³ twice to eliminate persistent types of *Staphylococci* and *Salmonella*. Roberts and Wilson¹⁴ claim that daily examination of workers for sores and head colds will help to avoid introducing *Staphylococcus* organisms during preparation of frozen foods, and they strongly advocate regulations for the care and handling of

cream fillings during and after preparation. These precautions should be heeded by producers of frozen precooked foods and bakery items.

PATHOGENIC ORGANISMS

While English investigators indicate that certain strains of *Salmonella* may produce enterotoxic substances, this has never been shown in American laboratories. Accordingly, *Salmonella* are considered as only pathogenic and not toxigenic in the following discussion. Because of the serious illness which may be caused by these organisms, the aim of the producer of frozen foods must be to eliminate entirely the possibility of the product becoming contaminated by germs of human origin.

Salmonella is the most important cause of diarrheal diseases according to Rubenstein, Feemster, and Smith,¹⁵ who found that four types of *Salmonella* were responsible for 70 per cent of 811 cases investigated. Although all age groups were involved, children were most susceptible. Convalescents and permanent carriers are frequently the cause of food infection with *Salmonella* organisms.

Segalove and Dack,¹⁶ after inoculating *Salmonella enteritidis* experimentally into string beans, tomato juice, peaches, shrimp, salmon, corn, spinach, and peas, and incubating them at 22° and 37° F., noted unexpectedly that better growth occurred at the lower temperature.

Ostrolenk and Welsh¹⁷ proved that *Salmonella* contaminated food may be the source of infection carried to other foods and water by means of flies. They showed that flies carried viable organisms as long as 4 weeks. Moreover, the fly passes the organism on to succeeding generations by infecting its eggs.

Food handlers were shown to be the major source of *Salmonella* poisoning in a study conducted by W. S. Stone¹⁸ who found 44 *Salmonella* carriers and 5

Shigella carriers out of 2,000 food handlers. These handlers, generally asymptomatic themselves, were associated with several small epidemic outbreaks.

Army investigators¹⁹ discovered that carriers of *Salmonella oranienberg* can be successfully treated with sulfaguanidine. Therefore, examination of handlers is not merely academic since such sources can be eliminated through positive therapeutic action.

Although the Kaufman-White²⁰ test has been used as an objective method of differentiating non-pathogenic and pathogenic strains of *Salmonella* by Edwards²¹ and others, the question of whether *Salmonella* of animal origin are pathogenic to man has not yet been answered. Investigators have always considered this as a possibility, but no direct evidence has ever been found to prove it. However, studies have described an outbreak of *Salmonella* infection allegedly derived from internally contaminated chicken eggs.

There have been certain indications that *Salmonella* organisms not only survive freezing storage but remain sufficiently viable to cause gastrointestinal infections, but there is a question that this is possible. The frozen food industry should attempt to prove this beyond any doubt.

The Enterococci and other gastrointestinal bacilli may or may not be implicated in food infections from frozen foods since direct evidence appears to be lacking. However, the protection of spoilage usually associated with food intoxications does not apply against infections, and extreme precautions against contamination are necessary.

INDUSTRIAL CONTROL PROCEDURES

The frozen food industry thus far has failed to establish a sanitary code to protect itself and its customers. A committee of the A.P.H.A. has recommended using the M.P.N. (most prob-

able number)⁵ or/and ²² value as a measure of human contamination of frozen foods. Various states have established sanitary codes for shellfish and in such foods the raw products are controlled to some extent.

The writer has felt that an industry standard of 100,000 organisms per gm. incubated on tryptone glucose extract agar for 72 hours at 30° C. might be difficult to maintain. After he saw a plant which can handle more than a million pounds daily of some products, meeting a standard of 10,000 per gm., he feels firmly convinced that the industry can set up the above standard for fruits, vegetables, meats, fish, and poultry, and an objective of 250,000 per gm. on hamburger, sausage, and similar products. Furthermore the direct count method such as that of Breed⁵ and/or ²³ on milk should be used as an additional standard to determine the original condition of raw materials for all products processed by heat prior to freezing. A standard microscopic count of 1,000,000 per gm. or ml. should be considered maximum.

Simultaneously, contamination with organisms of human intestinal origin should be measured against a standard. A maximum M.P.N. value of 100 may seem high for most products. In shellfish²⁴ a value of 230 is interpreted as indicative of unfavorable conditions.

SUMMARY

Frozen foods have been remarkably free from suspicion of being health hazards both as to enterotoxic food poisoning and infectious diseases. An acid-forming streptococcus appears to be an active factor during spoilage, souring foods beyond edibility before enterotoxins can be elaborated. However, there is considerable possibility that pathogenic organisms may survive the freezing-storage treatment and retain sufficient viability to cause infectious diseases. These could be a source of

infection in frozen foods of the very best quality because the souring would not be present to warn the user. Frozen fruits and vegetables which may be served in raw salads, could very well be the source of infections. These can be controlled only through careful sanitary procedures in factories.

Laboratory methods of detecting the incidence of toxigenic or pathogenic strains of organisms are presently inadequate, and frozen foods may momentarily be implicated as health hazards. The industry, accordingly, has every reason to support thorough research designed to develop control techniques.

It is difficult without human test subjects to show through laboratory studies the effect of freezing, time of storage, type of substrate or growing medium, temperature of storage and other factors upon the viability of known toxigenic and pathogenic microorganisms, relative to production of enterotoxins and to pathogenicity. While the frozen food industry is at least no worse off in this regard than other food industries, as a relatively new development it could be very seriously affected should a major epidemic be laid at its door.

A review of the foregoing should not make the frozen food industry feel more secure, but rather should encourage it to accept the responsibility for increasing the scope of research devoted to solving the several important problems outlined.

ACKNOWLEDGMENT—The writer wishes to express grateful acknowledgment of the assistance of Miss Ruth Adamy in searching the literature on the subjects of Botulism, Staphylococcus food poisoning, and Salmonella infectious outbreaks.

Current Trends in Nutrition Research in Canned Foods*

R. W. PILCHER, PH.D., AND B. S. CLARK, D.Sc.

Research Division, American Can Company, Maywood, Ill.

FOR more than 25 years reports in the literature have dealt with various phases of nutrition research on canned foods. Most of these reports group themselves into three distinct patterns of research. In the first of these may be classed those studies seeking to establish the nutritive values of commercially canned foods with particular reference to their vitamin contents. The second pattern includes investigations designed to establish the effects of conventional canning procedures or operations on vitamins present in raw foods. The third pattern comprises studies devoted to establishment of the stability of vitamins in canned foods during storage or usage. Investigations of these three general types have significant public health implications because in the ultimate analysis they relate to the improvement of the nutritive quality of canned foods as consumed by the American public.

The importance of these several patterns of investigation is further reflected by the fact that they have constituted the main fabric of the current nutrition program on canned foods jointly sponsored by the National Canners Association and the Can Manufacturers Institute. This program, which has been elsewhere described,¹ was conceived

prior to Pearl Harbor and inaugurated during the first year of the recent war. The National Defense Program of 1941 created a demand for more complete information on the nutritive values of canned foods and provided the direct stimulus for later inauguration of the program. In 1942, the wartime need for such data developed a high degree of coöperation between industry and educational institutions with the end result that an impressive volume of information on the nutritive values of canned foods was rapidly accumulated during the war years. The data thus far published as a result of this program will be considerably amplified by the end of 1947 through publication of the results of studies recently completed or currently in progress.

It is anticipated that work in these three phases of nutrition research will continue for some years to come, despite the great advances in knowledge made during the war, because of the sustained interest in these fields on the part of various laboratories associated directly or indirectly with the canning industry. However, during recent years our laboratory has engaged in specialized activities within these phases which were prompted either by new processing or equipment developments or by new interests arising as a result of the operations of the National Canners Association-Can Manufacturers Institute program. It is the purpose of this report to describe briefly several of the more

* Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Cleveland, Ohio, November 12, 1946.

important of these new departures which have concerned our laboratory during the past several years. In particular, projects which appear to have an ultimate public health importance have been selected for discussion.

EVALUATION OF MANUFACTURING OPERATIONS

In the investigations made under the NCA-CMI program, the 1942 and 1943 studies dealt chiefly with the vitamin values of commercially canned foods as manufactured, and with the effect of conventional canning operations on vitamins in raw canning stocks. These studies were carried out by extensive surveys of commercial plants and products. The findings suggest that, in general, those foods which were significant providers of certain vitamins in the raw state were also significant contributors of those same vitamins in the final canned product.¹ Tests on the effects of canning operations on vitamins in raw canning stocks have shown that the extent of the effect varies with the nature of the product and with the vitamin under consideration. Moore, et al.,² Wagner and Associates,³ and Lamb⁴ have found that the degree of retention of ascorbic acid in canned citrus products is consistently high during conventional canning. However, as indicated by other reports,^{5,7} vitamin retentions in the case of certain other standard canned food commodities showed a considerable degree of variability, with particular reference to ascorbic acid. The more important reasons for these variations in ascorbic acid, which in the case of certain items approached the tenfold value, have been reviewed by Jackson, et al.,⁸ and by Feaster and Alexander.⁶

For nearly ten years, field surveys of canning operations had largely been conducted as a result of the interest of laboratories connected with the industry rather than as the result of the practical interest of canners. As notable excep-

tions, of course, must be noted those manufacturers producing special purpose foods or foods exceptionally high in specific nutrients, or those seeking A.M.A. Council on Foods and Nutrition acceptance for their products. However, publication of the early results of work in the NCA-CMI program led to an awakened interest on the part of canners as to the efficiency of their own operations since, for the first time, a basis of comparison for the products of the industry as a whole was available. Canners whose products or plants had not been included in the studies desired to know how their products or operations compared with those reported; others sought to learn how existing operations might be improved so as to place their products in a more favorable position with respect to vitamin values or vitamin retention. Interest was particularly manifest in ascorbic acid because of the A.M.A. Council on Foods and Nutrition requirement for a minimum vitamin C value in Council-approved ascorbic acid carriers. An increased number of requests from canners for field surveys of factory operations have therefore been received by many laboratories associated with the industry.

In Table 1 are shown results typical of many of those obtained in such field surveys. The three plants listed were operated by one manufacturer; the canning lines surveyed were of conventional types differing only in detail; the basic equipment, operations and supervision were of one general pattern. While all samples assayed can be considered significant sources of ascorbic acid, variations in the per cent retentions, even in the same plant, are wide. In these particular instances, the occasional slow speed of cannery operations was the major factor influencing low ascorbic acid retention. Variations in vitamin C retention of from 52 to 80 per cent in tomato juice canning operations have

TABLE 1
Ascorbic Acid Retention in Tomato Juice During Canning

Plant	Survey Number	Content Mg./100g.	Ascorbic Acid	
			Retention * Per cent	Per cent Daily Allowance † 100 Gram Portion
1	1	18.2	81	24
	2	14.8	67	20
	3	18.4	69	25
2	1	12.3	54	16
	2	13.7	52	18
3	1	9.4	44	13
	2	12.5	61	17

* Based on chopped tomatoes

† Based on 75 mg. daily adult allowance

been described by Guerrant, et al.⁷ Results of 1943 and 1944 surveys conducted by Lamb⁹ showed ever greater deviations, namely, 32 to 94 per cent.

It has become clearly apparent that much may be accomplished toward improved vitamin retention merely by more effective operation of existing equipment. Surveys such as the one described have proved convincing to practical cannery management. Likewise effective has been expression of the results in terms of the percentage of the daily vitamin requirement supplied by convenient portions of the final product. Such a method of expression translates improvements in operations directly into an understandable benefit to the consumer which will accrue from such improvements. In this way, the basic reason for effective operations is made more apparent, much more so than simple statement of the findings showing vitamin content on a percentage or on a volume or weight basis. Sustained surveys of this type over several years should result in distinct raising of nutritive quality levels in many canned foods.

EVALUATION OF NEW HEAT PROCESSING TECHNIQUES

During recent years, there have been several important practical applications of new heat processing techniques. It should be frankly stated that these developments have come about more

from interest in improved organoleptic quality in the final product or improved control of operations than from the consideration of improved vitamin retention. Whatever the initial purposes of the developments, study of these new techniques from the nutrition standpoint represents a new trend of investigation, and the results of several of these studies may be of interest here.

PRESTERILIZATION OF ACID VEGETABLE JUICES

For a number of years, sporadic spoilage has been experienced by canners of tomato juice or vegetable juices consisting largely of tomato juice, due to heat resistant spore-forming organisms capable of causing the "flat sour" type of spoilage. As made clear by Pearce¹⁰ and by Williams,¹¹ the heat process commonly employed in the conventional canning procedures will not prevent spoilage due to such organisms, and their control depends upon observance of strict precautions in the plant.

As a result of work begun in 1940, Wessel and Benjamin of this laboratory suggested in 1941 a new means for process control of these organisms, which has now come into widespread commercial use.¹² In this new processing technique, the juice is heated by pumping through a suitable type of heat interchanger to temperatures in the range of 250° to 285° F., and is held at the elevated temperature for a few seconds

in order to effect the desired sterilization, and is then cooled and filled into cans at temperatures between 190° and 205° F. The sealed cans are inverted or are given a short boiling water process to sterilize the top can end and water cooled. The first commercial installation for this new so-called presterilizing or "flash" processing technique was made in 1941, but in 1946 more than 50 such installations were in commercial operation with complete success. The quality of the juices subjected to this high temperature—short time sterilizing process or flash process is entirely comparable to juice packed by the conventional process. Figure I shows schematically the salient differences between the conventional and the new flash processing methods for tomato juice.

Commercial use of the presterilizing process raised the question of whether it would favor greater retention of vitamins, particularly of thiamin, in the acid products for which it is used than does the conventional procedure, since high-short processing has been found to favor vitamin retention in certain low-acid products.⁸ Work in 1944 and 1945, however, suggests that the ranges of thiamin and of ascorbic acid

retention in tomato juice are practically identical for both procedures and that any major differences found in the overall procedures may be ascribed to factors other than time and temperature of processing. Data on thiamin retention during flash and conventional heat processing operations are shown in Table 2.

TABLE 2

Thiamin Retention in Tomato Juice
Effects of Flash and Conventional Processing

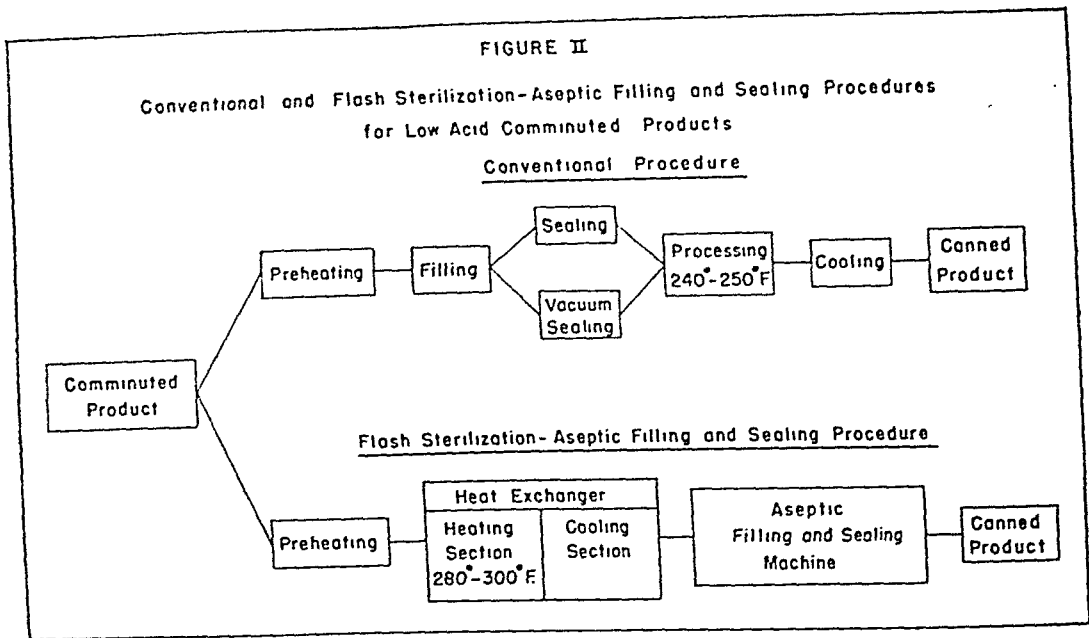

Type Process	Number of Surveys	Range of Thiamin Retention During Processing † Per cent
Conventional *	5	82 to 110
Flash	3	87 to 102

* 307 x 409 cans

† Based on the thiamin content of the juice before processing

FLASH PROCESSING—ASEPTIC FILLING
OF LOW ACID PRODUCTS

Another new type of flash processing adaptable particularly to low-acid products capable of being moved by pump through a tubular heat interchanger came into commercial usage shortly before the outbreak of war. This procedure is especially well adapted to the packing of low-acid vegetable purees, strained foods, certain dairy products,

and other foods of a semi-solid consistency. In many instances this technique has yielded products distinctly higher in quality than those produced by conventional means. It has further made possible the canning of commodities whose quality would be entirely unacceptable to consumers if processed by conventional procedures. Figure II broadly compares this new process with the conventional procedures for vegetable purees commonly employed. As will be noted, in this new method of processing the sterilized food and the sterilized can meet in the aseptic filling and closing machine where the filling and double-seaming or sealing are carried out. Thus, the quality of the final product in this procedure is independent of can size. In the conventional method of processing, food is heated in the sealed can. To effect sterilization, heat must penetrate from the body and ends of the container to the food in the center of the can. This rate of heat penetration is quite slow for food products which heat largely or solely by conduction; likewise the rate of heat penetration into large cans is slower than into small cans of the same conduction-heating product. This means that at conven-

tional process temperatures (240° or 250° F.) the process times required for the larger can sizes are much longer than those necessary for the smaller container sizes. The product quality in the large containers is therefore invariably lower than the same product packed in the smaller can sizes.

The influence of the high-short type of process on vitamin retention in low-acid foods has been under investigation in this laboratory since 1932. Some of the results obtained have been reported elsewhere⁸; likewise the effects on vitamins of high-short processes with sterilizing values (F_0 values) several times higher than those used conventionally have been described.^{13, 14} Briefly stated, in the high-short processing of low-acid, conduction-heating products, the ratio of the rate of thermal destruction of bacteria, capable of causing spoilage, to the rate of thermal destruction of certain of the vitamins is considerably greater than the similar ratio in conventional processing of the same product.

The relative effects on thiamin of the flash-aseptic filling and closing process and the conventional procedure on pea puree and cream style corn are shown

TABLE 3
Thiamin Retention During Flash and Conventional Processing

<i>Product</i>	<i>Type Process</i>	<i>Process Order ° F.</i>	<i>Thiamin Content Mg./100 gm.</i>
Cream Style Corn	Conventional	6	0.040
	Flash	26	0.101
Cream Style Corn	Conventional	9	0.025
	Flash	26	0.053
Pea Puree	Conventional *	5	0.180
	Flash †	24	0.2214

* Composite of 6 cans (211 x 413)

† Average of 10 individual cans (211 x 413)

in Table 3. Except for the manner of thermal processing, these purees were identical and the superior retention of thiamin by the flash process is clearly suggested by the data. This new processing technique is to be extended to many canned products for which it is suited.

AGITATED VACUUM PACK FOR LOW-ACID VEGETABLES

The vacuum packing of certain low-acid vegetables has been a commercial procedure for a number of years. This style of pack, widely used for whole grain corn, is differentiated from the more familiar "brine style" pack first, by the higher ratio of solids to liquids in the can, and second, by the use of vacuum sealing for the container. In the brine style pack, after the corn has been filled into the can, the fill of the container is completed by brine. In the vacuum pack only 1 to 2 oz. of brine are added to the can. During heat processing, the moisture in the evacuated can is converted to steam which serves as the transfer medium. The heat process required commercially for the vacuum packed 307 x 306 can of whole grain corn (35' @ 250° F.) is more severe than that necessary for the brine packed No. 2 can of the same product (25' @ 250° F.) although the drained weights of both containers are closely similar.

Equipment has been available for many years for agitation of cans during

processing in order to increase the rate of heat penetration into the can and thus shorten the process time required. Over the past two years experimental work was carried out in our laboratories to determine the possible benefit of agitating vacuum packed products during processing. Agitation in products of this type increases the rate of heat transfer within the vacuum sealed container and thus permits adequate sterilization in a much shorter time than when the product is processed without agitation. Conceivably, this shorter process time might influence color and flavor of the final product. Actually, distinct quality advantages to both white and yellow vacuum packed whole grain corn were found to result and this type of process became commercial for corn during the 1946 season.

To test effects of this new processing technique on vitamin retention, controlled experiments were carried on on whole grain corn during the 1946 season. The results of two series of experiments are shown in Table 4 covering the two can sizes used commercially. For direct comparison, brine style, still-processed vacuum, and agitated vacuum packs were made in the same size of container and the thiamin and niacin contents of both the solid and liquid phases in the cans were determined in order to arrive at the total amounts of these vitamins in the containers after processing. In this way, correction was made for loss of vitamins from the solid

TABLE 4
Vitamin Retention in Canned Yellow Whole Grain Corn
Effect of Style of Pack

Series	Style Pack	Can Size	Process Schedule		Vitamin Retention *	
			Time Min.	Temp. ° F.	Thiamin Per cent	Niacin Per cent
1	Brine	307 x 306	25	250	68	106
	Vacuum	"	35	250	51	95
	Agitated Vacuum	"	12	250	75	94
2	Brine	603 x 408	40	250	61	94
	Vacuum	"	60	250	33	98
	Agitated Vacuum	"	17	250	51	99

* Based on the vitamin contents of the corn before processing

to the liquid phases by solution or extraction during processing.

The data in Table 4 indicate that agitation of vacuum packed yellow whole grain corn during processing increases thiamin retention over that attained in the orthodox or still-processed vacuum style of pack. Thiamin retention in the brine style and agitated vacuum packs appeared approximately equal; other series not reported here, however, have indicated a somewhat greater thiamin retention for the new processing technique. Niacin retention in the product appeared not to be influenced by the style of pack. Besides the quality advantages to vacuum packed whole grain corn bestowed by the agitating process, a higher retention of thiamin than that achieved in the conventional vacuum pack method is clearly indicated.

CONCLUSION

An attempt has been made to present typical studies currently included in nutrition research on canned foods. Certain of these appear to have distinct public health implications since they should ultimately lead toward even greater degrees of vitamin retention in certain canned foods than are now attained commercially.

Acknowledgment—Appreciation is expressed to Drs. J. F. Feaster and Margaret Ives and Mrs. Marshall Tompkins for the data included

in this manuscript and to Miss Edwyna Preiss for her valued assistance in its preparation.

Proposed Report on Field Training of Public Health Personnel*

THE proper training of public health personnel requires not only formal academic training but also the opportunity to study the field application of the principles learned in the classroom. Field observation and study are to public health education what the student laboratory and internship are to medical education.

It would, therefore, be desirable to incorporate a period of field training as a part of formal education provided by various accredited schools and universities. Such a period is required in the training of public health nurses and is required by some universities for other types of personnel. To require such experience for all personnel is not feasible today because of the lack of a suitable number of areas within which such training may be obtained. It is essential, therefore, that suitable field training areas be developed and that these areas attain certain standards as evidence of their capacity to serve as student training centers.

It is apparent, however, that great variation exists in form and objective of field training. The student who merely visits a health department for a few

hours a day is undergoing a very different educational experience from that of the student who spends several months as a junior employee; yet each is experiencing field training. Each type has its place, yet the purpose served by each is very different. The types of field training and the objectives of each type are set forth below.

Equally apparent is the fact that every public health agency is not suitable for the purpose of field training. Such training requires not only the conduct of a health program worthy of study and demonstration, but also personnel who have both time, willingness, and ability to accept students for training. Just as certain hospitals are not suitable for the teaching of nursing or the training of interns or residents, so certain health departments may not be acceptable agencies to conduct public health training. Similarly a department capable of furnishing a certain type of field experience may not be capable of offering other types of training.

The committee has attempted, therefore, to establish certain standards which may serve as a guide in the development of field training areas. The committee recognizes that these standards are, of necessity, provisional and in many instances reflect a lower quality of service than might be desired. On the other hand, it has been forced reluctantly to accept the fact that many field training areas in all parts of the United States do not attain even these minimum standards. Like all other standards, they should be raised at a later date when

* The Committee on Professional Education of the American Public Health Association publishes this report before transmittal to the Governing Council in order to permit the members and Fellows of the Association to review it and to offer criticisms and suggestions in the further consideration of the report. Suggestions should be mailed promptly to the Committee on Professional Education, A.P.H.A., 1790 Broadway, New York 19, N. Y.

This report, like all other statements of the committee on professional and technical qualifications in public health, is subject to periodic revision in order that it may be kept abreast of the best thought.

the quality of service that they attempt to measure has been suitably improved.

The committee likewise recognizes that there is at present a great dearth of suitable field training areas. This dearth has necessitated the utilization of facilities that are lacking many of the features that should be required of all field training areas, and at the same time has prevented the schools of public health and the universities from requiring the amount of field experience that they would otherwise desire. This lack of facilities is found in all parts of the United States.

The shortage has been brought about in part by the fact that field training is expensive under all circumstances and especially if it is to maintain suitable standards of quality. The quality of health service performed by the agency must be high, a fact which in itself implies appreciable expenditures. In addition, the presence of students is time consuming to the staff. Yet unless the staff members devote certain time to their training responsibilities, the student can learn but little from the experience. Proper field training, therefore, usually necessitates the employment of additional staff to assume direction for the training or to compensate for the time devoted to this activity by the regular staff. While the training area benefits from the stimulus of student visits, criticism, and participation, it is believed that the added expense should not be carried by the local community that is already supporting a health program of high quality. It would seem reasonable that the added expense should be assessed against the general cost of public health education. The universities, however, cannot be asked to carry the financial burden of providing field training. Their funds are extremely limited, drawn largely from limited endowment or from the taxpayers of the few states in which the universities are located. These funds must be used to

carry the mounting costs of formal academic classwork. The small sums that they can afford to pay for field training charges cannot be appreciably increased without new sources of revenue; at present these fees are grossly inadequate to recompense the community for its added expenses incidental to the development of proper field training facilities. Were the added costs to be paid by either the university or the state, the facilities would inevitably become limited to reception of students from certain colleges or states. This would not only result in an uneven distribution of costs but also result in undesirable provincialism.

The committee is, therefore, of the opinion that the cost incidental to the development of better field training facilities should be borne by the federal government except for those areas offering opportunities only for observation and orientation, which are considered to be state responsibilities. Federal interest in public health training and education has already been expressed in the provisions for training stipends. It is, therefore, recommended that additional grants be made through state health departments for the specific purpose of developing in some states one or more field training areas which will offer to persons, irrespective of school or residence, the types of training set forth in this report and will meet the standards likewise set forth herein.

DEFINITIONS AND OBJECTIVES OF FIELD TRAINING

Field training is defined as an opportunity to study the field application of the principles and practices of public health. There are several types of field training, each of which is designed to serve a distinct purpose. These types are:

A. *Observation*

Definition—A planned visit to a health agency to observe the pub-

lic health program without active participation therein.

Objective—To see the functioning of an efficient community health program. The duration of the visit is usually brief (one to a few days). The planning is individualized on the basis of past experience and special interests. Observation may be of value to the uninitiated as well as to the highly skilled.

B. Orientation

Definition—Preparation of a person for a specific job under the auspices of the employing agency.

Objective—To acquaint the prospective employee with administrative details and policies of the employing and related agencies and the conditions under which he is to work; for example, background, laws, regulations, records, personnel, and health problems of the area. The duration of a planned period for orientation is usually a matter of a few weeks.

C. Supervised Field Experience

Definition—Planned instruction observation and active participation in a comprehensive organized public health program as an integral part of or a sequel to formal academic training in public health.

Objective—To learn to apply the basic principles and skills studied in a university course to actual field situation. It may or may not be a requirement for an academic degree. The duration of a planned period of Field Experience is usually from 2 to 4 months.

D. Apprenticeship

Definition—An extended period of active service under supervision in a public health program but without prior academic training in public health.

Objective—To select personnel best suited for formal academic training, to prepare them to receive the maximum benefit from such training and to develop certain elementary skills by participation in the public health program as assist-

ants to qualified workers in their professional field. The period of apprenticeship is usually for a period not to exceed one year.

E. Residency

Definition—An extended period of active service under supervision in a public health program following a period of formal academic training in public health.

Objective—To develop through supervised practice a high degree of technical skill and confidence in a person who has had broad basic academic training in public health. This is usually accomplished through occupancy of a first level staff position in an organized health agency already employing competent supervisory personnel. It corresponds to the year of supervised experience required in public health nursing and is comparable to the residence required for certification in medical specialties. It may or may not be a requirement for an academic degree.

MINIMUM STANDARDS FOR FIELD TRAINING AREAS

I. TYPE OF AGENCY

- A. Well organized and well established official local health department, either county, city, or district, or
- B. Well organized and well established official and nonofficial agencies in which there is joint planning of the training program.

II. UNIT OF POPULATION SERVED

Although no unit of population is specified, experience shows that areas of less than 25,000 population are rarely qualified to give suitable field training. In large units serving several hundred thousand persons or more, it is customary to select certain areas within the unit to be developed for student programs.

III. LOCATION AND TYPE OF AREA

- A. The local area should present a cross-section of typical health and

administrative problems for that section of the country in which the area is located.

- B. The field training area should be located in a state having the necessary facilities to give strong leadership and close supervision to the project.
- C. For orientation the area preferably should be located in the state in which the person is to work.
- D. The area selected for supervised field experience should present problems comparable though not necessarily similar to those of the area in which the student will return upon completion of training. Training need not be given in the same or a contiguous state. There should be joint planning, evaluation, and coordination of student academic and field work between educational institution and field training center.
- E. For apprenticeship and residency any local unit which qualified as a field training area so far as concerns the basic service program and quality of staff may be used.

IV. BASIC SERVICE PROGRAM

- A. A comprehensive program should be planned on a community-wide basis in cooperation with other community agencies and based upon a careful study of local health problems. It is desirable that the community plan should be based on facilities and needs for preventive, hospital, and medical care services.
- B. The activities of official and non-official agencies should be coordinated into a community-wide program. The students should have experience in working with all types of agencies in the community contributing to the health, welfare, and education of the people.
- C. The state health department, in cooperation with the local unit, should plan for periodic program evaluation based upon evaluation

standards of the American Public Health Association.

- D. The scope and quality of the public health program should be above the median in at least half of the applicable items as set forth in the *Health Practice Indices 1943-1944* prepared by the Committee on Administrative Practice of the A.P.H.A. August, 1945, and within the first quartile for at least half of the items applicable to the work of the students for whom training is contemplated.

V. PERSONNEL

- A. The number of personnel should be adequate to provide local services and educational experience for the students. The desirable number of personnel should be not less than—
 - 1. A full-time medical health officer and medical service, either full- or part-time equivalent to one medical officer per each 50,000 persons in excess of initial 50,000 population.
 - 2. One nurse at the supervisory level for every unit of ten or less staff nurses.
 - 3. One staff nurse per 5,000 persons (exclusive of complete bedside nursing care).
 - 4. One sanitation worker with graduate training in public health who, if not a public health engineer, should be supervised at the state, district, or local level by a qualified public health engineer who participates in the students training program, and one sanitarian or sanitary inspector per 15,000 population in excess of initial 15,000 population.
 - 5. The services of a health educator either as a member of the staff or available on a state or district basis.
 - 6. One stenographic, clerical and

record person per 15,000 population.

7. An educational director for each type of personnel received for training, such director to be available either as a member of the local staff or as a member of the district or state staff with special responsibilities for training duties.

B. The staff of the health department should meet professional standards established by the Committee on Professional Education of the American Public Health Association, National Organization for Public Health Nursing, and other national voluntary professional groups, the U. S. Public Health Service, and the state merit system in which the area is located. Members of the staff who deal with students should be qualified by education and experience, and should be mature, emotionally stable persons who are interested in teaching.

VI. STUDENT LOAD

- A. Observation—no formal limitations in number but too frequent visits may impair efficiency of unit.
- B. Orientation, apprenticeship, and residency—no formal limitations in number but in general more students can be accepted at any one time than for supervised field experience.
- C. Supervised field experience—in general, not more than one student at any one time per corresponding qualified staff member.
- D. It is desirable that the total number of students at any one time, other than for observation, should not exceed the rate of one per corresponding staff member.
- E. No staff member should have continuous direct student supervision responsibilities (throughout the entire year) for more than 9 months out of the year.

VII. RESPONSIBILITIES OF VARIOUS AGENCIES

A. State Health Department—

1. To help plan and evaluate the basic and field training programs.
2. To provide general supervision and consultation. In large urban units the general supervision and consultation service may be given largely by the central staff of the local health department.
3. To assist with the coordination of academic and field training programs.
4. To assist in providing in-service training for staff members participating in the student program.
5. To serve as a field training student placement clearinghouse for all agencies within and without the state.
6. To be responsible for securing adequate financial support for the training program based on cost analysis of the program.

B. Local Health Department—

1. To maintain a basic service program so that the area will qualify as a field training area according to standards listed above.
2. In cooperation with the state department of health, universities, colleges, and other agencies using the area, to plan, develop, administer, and evaluate the educational experiences provided for the students.

C. University, Colleges and Other Agencies Using the Area—

1. To determine individual student needs and to assist in planning of educational experiences for students.
2. To assist with coordination of academic and field experiences.
3. To assume such financial responsibility for student training as may

be agreed upon with federal, state, and local health agencies.

D. Federal Agencies—

1. To help finance field training areas through financial grants-in-aid by way of the selected

state department of health or educational institutions.

2. To act in a general advisory capacity to the state or local agencies through the the regional offices of the federal agencies.

A New Method of Selecting Health Officers-in-Training

MARGARET W. BARNARD, M.D., DR.P.H., F.A.P.H.A., AND
WILLIAM BRODY

*Director of District Health Administration; and Director of Personnel;
Department of Health, City of New York*

THE candidates seated themselves around a table and conducted their own examination. The examiners just watched and listened. This was the new method which the New York City Department of Health used in selecting its new Health officers-in-training.

Proper selection of individuals for the Health officer-in-training group is a matter of concern both to the individual and to the department. The training course itself is of two years' duration, at a stipend level, and the individual pledges himself to remain two years in the field for which he is trained. A decision to enter this training course is a serious one, often involving considerable readjustment of personal and family plans. The trainee who is selected has the right to feel that those responsible for his selection believe he will make good in his new career venture.

The department is concerned with training career men and women for positions in public health administration or as executives in specialized fields. Each candidate has given evidence of adequate basic training in medicine; whether he possesses the aptitudes and potential skills necessary for a successful executive officer in public health is the problem of the examining committee. Public Health knowledge is not required, for the successful candidate will undergo two years of specialized train-

ing in this field. More important factors are intellectual curiosity; the ability to reason logically, to present facts clearly to others, and to make one's point without arousing antagonism; leadership ability; easy acceptance by a group as a desirable participating member; an awareness of broad social and community problems and trends; an "engineering sense" in attacking problems; and adequate reasons for wishing to specialize in a particular field. These and a host of others are the intangible but tremendously important qualities inherent in the successful career individual in public office. Usually, written examinations are employed to test knowledge of subject matter and subsequent oral examinations are employed to evaluate such traits as those mentioned above. It is believed that the group oral performance test described in this paper offers a novel means of evaluation which is more effective than the traditional examination techniques.

THE POSITION

Health-officers-in-training are nominated by the Department of Health, subject to approval by the Municipal Civil Service Commission, for a two year training course. Eight months of this will be in a school of public health, leading to the degree of Master of Public Health. Each trainee is also

given a 16 month orientation course within the Department of Health. Tuition fees and a stipend for the two year program are paid for out of funds made available by the U. S. Public Health Service.

Those who complete the program are eligible to participate in a competitive civil service examination for the position of assistant district health officer (\$4,500 per annum and over).

The minimum requirements for the position of health-officer-in-training are:

1. United States citizenship.
2. Graduation from an approved medical school.
3. One year internship or residency in a general hospital approved by the American Medical Association (except that those applicants whose internship or residency had to be reduced because of the war emergency shall be required to have nine months' internship or residency in a general hospital approved for internship by the American Medical Association).
4. Eligibility for license to practise in New York State.

THE CANDIDATES

Candidates for these positions are secured by means of a continuous recruiting program. Directors of the various bureaus of the Department of Health are always alert to the development of potential health officers among their staff physicians and among the applicants for medical positions. Administrative officials in schools of public health are aware of this program and refer some of their most promising students and applicants for consideration.

Each candidate is interviewed personally by the Director of District Health Administration when he first presents himself. This interview lasts for approximately an hour and serves the dual function of discouraging those who are obviously not qualified and encouraging those who seem qualified.

THE PRELIMINARY EXAMINATION

All candidates who had received this personal interview during the four month period since the previous examination for this position and who had become sufficiently interested to file applications were invited to an "experience interview test." Each of the twelve candidates who responded was interviewed for a period of approximately 15 minutes by a board of examiners consisting of three staff members of the Department of Health (the Director of District Health Administration, the Director of Personnel, and a Senior District Health Officer), and Dr. Thomas Dublin, Professor of Preventive Medicine at the Long Island College of Medicine. This interview served the purpose of eliminating those candidates who were unable to meet the minimum requirements as well as those who, in the judgment of the examiners, were obviously not qualified for the training program. Four candidates were eliminated at this stage.

THE PREPARATORY MATERIAL

Each participant in the preliminary examination was given a set of instructions which (1) explained the purpose of the experience interview, (2) pointed out that those who seemed best qualified would be summoned for a "group oral performance test" five days later, (3) indicated that results of the preliminary test would be available within two days, and (4) stated that as part of the group test, "each of those summoned will be called upon for the following:

I.

You and the other members of the group, as leading physicians known to be interested in matters affecting the health of your community, have been invited by the Commissioner of Health of the City of New York to consider the following problem, and to give him group recommendations. These recommendations are to be forwarded to the Commissioner at the close of your meeting:

Rabies among animals is increasing rapidly. There are about 200,000 licensed dogs and

an estimated additional 200,000 dogs in the New York City area. What control measures should be taken?

II.

Assume that you have been called upon to deliver a talk of three to five minutes on whichever one of the following subjects you select. Deliver the talk as if the group specified were before you now.

1. You are attending a meeting of the Committee on Public Health of your County Medical Society. The committee has passed a resolution urging the City Department of Health to establish a post-war program for the control of tropical diseases. As a member of the committee you are called upon to express your views as to what the official health agency in the city might do toward this end.

2. You are attending a meeting of the Parent-Teachers Association of a private school to which you send your child. The subject of rheumatic fever is being discussed and you are called upon by the chairman to discuss the public health implications of rheumatic fever as it might involve this school.

3. The District Health Officer has requested you, as a leading physician in the community, to address a group of parents concerning the following problem:

A large number of veterans' families have moved into a local housing project. There are more than the usual number of babies and preschool children in this group. Although the District Health Officer believes that immunization is necessary, the parents have been slow to have this done.

4. You, as a leading pediatrician, have been requested to address a group of general practitioners in your County Medical Society on the rôle of the general practitioner in carrying out systematic health supervision and health promotion of well children.

5. The County Medical Society has requested you to speak as a representative of the Department of Health on the use of gamma globulin for measles.

6. At a Kiwanis luncheon you as one of the medical members are asked to tell the group about the present smallpox situation in New York City and advise them what to do for themselves and their families.

7. A community which has many mosquitoes hears that there are several veterans in a nearby hospital with malaria. The voluntary health agencies have become alarmed and have asked you to speak at a joint meeting of the members of these agencies to discuss the problem.

8. In a community close to which there is a large shipyard, venereal disease has increased suddenly and there seems to be in the community a correlated social disorganization. Discuss this problem in one of the following roles:

- (a) Medical officer of the shipyard to the employees
- (b) Venereal disease control officer of the area to leaders of civic agencies
- (c) Director of social hygiene to a management group
- (d) Venereal disease control officer to a women's club group

THE GROUP ORAL PERFORMANCE

TEST

The rating board for this test consisted of the same four examiners who participated in the experience interview. Two of them sat along each of the long walls of the examination room.

As the candidates arrived they were allowed to select their own seats around a conference table. As soon as all eight* were seated, each was given a single sheet on which was the same information as in Part I of the preparatory material, with the addition of the following two paragraphs:

You will be rated on the value of your contribution to the recommendations made, your approach to the problem, your group participation, and your manner and speech in presenting your opinions.

Speak clearly so that everyone can hear you. The group itself will decide how the discussion is to be carried on. Start the discussion as soon as everyone has finished reading this statement. Continue until a signal is given to stop.

No additional directions were given and no questions were asked by the examiners.

Within 2 minutes one of the candidates took the lead and before long all were participating in the discussion. After about 30 minutes they agreed to select one of their members as secretary.

About 30 minutes later the examiner in charge announced the conclusion of

* If more than ten or twelve candidates had been involved, it would have been necessary to divide them into subgroups.

that part of the test, and a 5 minute recess was taken.

The examiners then reversed their seats along the wall, while the candidates elected to resume the same seats at the table.

The material which was distributed to the candidates at this point consisted of Part II of the preparatory material, with the following additional comments:

After you have finished, the members of the group will assume that they constitute the group you have chosen and will ask you appropriate questions.

The order in which each individual is to speak will be determined by the group. The group will also decide how much time should be allowed for general discussion after each talk.

Start the discussions as soon as everyone has finished reading this statement.

Speak clearly. You will be rated both on your own presentation and on the questions you ask.

After a very brief discussion the group selected the first speaker and agreed to proceed in the same order as they were seated.

When the first speaker had concluded his talk, the group was at a loss as to how to proceed. It was obvious to the examiners that no candidate had read the last four paragraphs of the instructions, and it became necessary to direct the group to do so. If this development had been foreseen, it would have been a simple matter to place this explanatory material at the beginning of the instruction sheet.

Thereafter the program continued without complications. It may be of interest to note that every speaker exceeded the prescribed length of time for the talk (in one case the elapsed time was 15 minutes), but the group rigidly held to its self-imposed time limit of 5 minutes for general discussion after each talk.

The examiners had prepared a third problem similar in form, but not in content, to the first. This was to be given

to the group at the examination so that no previous preparation for answering could be made. However, the examiners unanimously agreed that they had learned enough about the candidates on the basis of the two prepared topics. The examination was concluded slightly less than 3 hours after it had begun.

SOME PERTINENT OBSERVATIONS

1. *Previous Experiments*—The technique of the group oral performance test is based upon methods developed by the British Army in selecting officers during World War II and experiments conducted by the Test Development Section of the U. S. Civil Service Commission under the direction of Mr. Milton M. Mandell.

2. *Advance Preparation*—One important variant introduced in the health officer-in-training test is the device of presenting the problems to the candidates in advance. This was designed to eliminate the advantage which might accrue to some candidate or candidates because of fortuitous special knowledge of the subject.

In this connection, two important factors should be noted. In the first place, this examination is not designed to test for knowledge. In the specific situation, a common basic knowledge of medical theory could be presumed because of the minimum requirements; no further knowledge was considered as important for selection purposes because successful candidates would undergo the two year training course.

In the second place, the ability of the candidates to gather appropriate data in the five day period after receiving the preparatory material was considered to be a significant element in rating.

The candidates were not given specific information about the nature of the test in advance. For example, they were not informed that there would be a general discussion after each individual talk.

3. *Name Cards*—Another innovation which is interesting if not quite so important is the use of name cards. Each candidate was furnished with a folded sheet of heavy cardboard (5" x 10") with his own name in large letters on two sides. This had the double advantage of enabling the candidates to address each other by name, thus minimizing the artificiality of the situation, and of insuring the examiners against assigning ratings to the wrong people.

4. *Rating Factors*—The examiners rated each of the candidates on each of six factors. Each examiner determined his final rating of each candidate by adding the six factor ratings and the experience rating (arrived at in the preliminary examination) and dividing by 7. The six factors and the elements considered under each factor were:

1. *Appearance and Manner*. Poise, physical alertness, nervousness, restlessness, attentiveness, mannerisms.

2. *Speech*. Power of expression, vocabulary, diction, modulation.

3. *Attitude Toward Group*. Tact, coöperation, ability to mix, flexibility.

4. *Leadership*. Ability to assume lead without giving offense; acceptance by group.

5. *Contribution to Group Performance*. Team-worker or prima donna; awareness of objectives of group discussion, ability to reconcile differences.

6. *Scientific Approach*. Ability to marshal data, awareness of implications, ability to reason, ingenuity, mental alertness, judgment.

5. *Seating Arrangements*—No chair was provided at the head (or at the foot) of the table. Therefore no one candidate could receive any advantage of apparent leadership due to seating. If the group had selected its own chairman, he could of course have moved his seat around to the head of the table. It was interesting that the group did not select any chairman.

The examiners were seated far enough away from the table to allow the group to forget (at least occasionally) that they were present, but not so far

away as to miss anything. At the intermission in the middle of the test, the examiners changed their seats to insure adequate opportunity to observe each candidate.

6. *Extent of Participation*—The degree to which each candidate participated was an important element of the examination. The technique of a brief individual talk was incorporated in the test specifically to insure adequate consideration of even those candidates who might not participate in the general group discussion.

7. *Results*—It was the unanimous opinion of the four examiners, as well as the independent judgment of each of three observers with testing experience but no medical background, that three of the candidates should be considered as not qualified for the training course, while the remaining five showed considerable potentiality. There was less agreement concerning the rank order of the five who were considered qualified. With the exception of one examiner, however, all placed two specific candidates in either first place or second place.

Advantages of the Group Examination—The group performance test appears to possess the following advantages over the ordinary oral personality interview:

1. It enables the rating examiners to observe each candidate in action for a period of 3 hours. In the same amount of examiner time each candidate could be granted an individual interview of only 20 minutes.

2. It permits each examiner to devote full time to observing, listening, and taking notes.

3. It eliminates any tendency on the part of examiners to use the oral interview to show what they know rather than to evaluate the candidates.

4. It prevents any loss of reliability caused by the use of different questions for different candidates as well as by information given to later candidates by those examined earlier.

5. It minimizes the effect of the inevitable lack of continuous concentration on the part of examiners.

6. It provides a more natural situation than the usual question and answer contest between a candidate and his examiners.

7. It eliminates any suspicion on the part of any candidate that other candidates may be shown favoritism, be given easier questions, or have a lucky break. It may even convince him that some other candidates are better qualified than he is.

8. It eliminates the following dangers in the conventional oral interview situations.*

- a. "There exists a tendency for panel members to slant their attention to the candidate's response to their own questions."
- b. "It has been found that the rating to any candidate tends to carry over positively to the following candidate. The consequence is a species of halo effect."

* Pointed out by Norman J. Powell, and Harold Levine in a mimeographed "Manual of Procedures in Oral Tests" prepared for the Civil Service Commission of the City of New York.

9. It provides very valuable information concerning the action of each candidate toward the other members of the group, as well as his reaction to their actions. This is particularly important in testing for positions where group discussions and conferences are essential.

10. It presents specific evidence concerning the ability of each candidate to be a leader in a group of professional colleagues.

11. Those who participate seem to find it more interesting than the individual interview. (Incidentally, this applies to examiners as well as candidates.)

12. It requires no skill in asking extemporaneous questions on the part of the examiners. The topics for group discussion or individual presentation are carefully prepared in advance and the examiners as a group are familiar with what may be expected as reasonably adequate discussion content and what particular points to look for in each topic.

Family and Community Living

Vassar College, Poughkeepsie, N. Y., announces its 22nd Summer Institute for Family and Community Living, July 9-August 6.

As its name implies this is a family school for parents, teachers,

and professional workers. It has facilities for 150 adults in its workshops and seminars and for 132 children in its children's school. Mary Fisher Langmuir, Professor of Child Study, is its director.

Baltimore's Community Rat Control Program*

JOHN T. EMLEN, JR., PH.D.†

Associate Professor, Department of Zoölogy, University of Wisconsin, Madison, Wis.

POPULAR demand for a reduction of the property damage and disease hazards caused by rats in residential communities, and a wartime need for extensive field tests with ANTU raticide have resulted in the development of an unusual type of program of rat control in Baltimore, Md. This program emphasizes suppressive measures as opposed to exclusion measures (rat-proofing), and is based on the fundamental premise that the rat population of a city block is essentially isolated so that it can be treated as an independent unit. Management of block programs including the execution of periodic eradication campaigns is, in most cases, handled by block residents themselves under the supervision of a central city organization. Business districts are treated as demands arise, but emphasis is placed on residential communities for which the system appears to be particularly applicable.

HISTORY AND SCOPE OF THE PROGRAM

About 200 residential blocks were used as a testing ground for new thiourea rat poisons by Dr. C. P. Richter in the fall of 1942.¹ Results in many instances were good and the recovery rates of the decimated rat population were unexpectedly slow. On the basis of these successes, the City of Baltimore undertook an ambitious city-wide program based on the block unit principle. An organization was set up in June, 1943, with a field crew of from 8 to 15 men, and about 1,877 city blocks were treated before the end of 1944. A system of volunteer inspectors was concurrently organized to report persistent infestations and reappearances in treated blocks, and to request follow-up treatments as needed. Many of the block campaigns completed during the period were highly successful; a few were unsuccessful.

Encouraged by a favorable public response, the work was reorganized as a Division of the Bureau of Street Cleaning on January 1, 1945. The program was continued in much the same manner as in 1944 except that new emphasis was placed on volunteer coöperators who were authorized to do the poisoning work in their home blocks after receiving appropriate instructions. By the end of 1945, 2,120 citizens had registered as volunteer workers in the program, and 4,160 city blocks had been treated one or more times with a total

* A municipal enterprise supported by city appropriation and established in January, 1945, as a Division of Rodent Control in the Bureau of Street Cleaning. Research studies were conducted partly under a contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and The Johns Hopkins University Medical School, and partly under a grant from the Rockefeller Foundation International Health Division to The Johns Hopkins University, School of Hygiene and Public Health.

† Contribution from the Rodent Ecology Research Project, Department of Parasitology, The Johns Hopkins University, School of Hygiene and Public Health, and The Psychobiological Laboratory, The Johns Hopkins Medical School.

of approximately 100,000 pounds of poisoned bait.

Special attention was given to repeat treatments during the first 6 months of 1946, but 964 new blocks were poisoned, raising the total of blocks treated to 5,574 out of about 6,800 in the city.

ENVIRONMENT

Baltimore is a thriving seaport city of 860,000 people, augmented during recent years by an additional 70,000 war workers. Residential structures in downtown areas are almost entirely row houses, two or three stories high, constructed of brick. Small, fenced back yards are usual, opening in the rear onto paved alleys which run through the center of each block and are used for collecting trash and garbage.

The rat population, all brown rats (*Rattus norvegicus*) except in a few waterfront buildings, averages about 75 per block in downtown residential areas.² This is believed to be roughly comparable with rat population levels in other cities along the North Atlantic Coast and in the Midwest. About three-fourths of the rats in residential areas live outdoors in yards, garages, and sheds, and one-fourth indoors; very few rats are found in the sewers.

PLAN OF PROCEDURE

Areal Units

The adoption of an essentially isolated areal unit was found to be fundamental to successful rat control in Baltimore. Eradication jobs in single "open" buildings and in small, non-isolated sections of a block have given very incomplete and temporary relief and frequently have led to prejudices against baits among surviving rats, a condition which seriously complicates subsequent control efforts.

Experiments with marked rats have demonstrated the essentially isolated character of a city block, the area bounded by four city streets²; and ex-

perience gained in poisoning over 5,500 city blocks has indicated the adequacy of this unit for control operations.

In most cases a plan is followed for coordinating eradication campaigns in neighboring blocks so that sizeable tracts are covered in a single operation. This is largely a measure for convenience and efficiency, for there is no indication at present that isolated blocks recover or are reinvaded any more rapidly after treatment than grouped blocks.

Organizing Block Rat Control Programs

Since January, 1945, the program has emphasized the scheme of getting citizens to do the work themselves with instructions and materials furnished by the city. Blocks are organized for treatment by soliciting interest among residents or by persuading those people who write or telephone the city office for help that the solution to their personal problem with rats lies in a community program in their block.

Once a person has been found who will assume the responsibility of organizing a block team, mimeographed bulletins prepared by the city on "How to Organize and Practice Community Rat Control" and "Rat Control in Urban Residential Baltimore" are forwarded together with a petition form which may be filled out and returned, ordering the baiting materials and instructions necessary for staging a community campaign.

Upon receiving a completed petition form, the city issues an identification card to the responsible leader who is designated as the "block captain." A community meeting may be scheduled and field demonstrations of eradication procedures are given by experienced city men before any work is undertaken.

Not all blocks are handled by volunteers. A city crew performs the work in cases of special urgency and in blocks where a local lack of public response has resulted in the leaving of heavy infestation spots in otherwise clean sections of the city.

Eradication Campaigns

The first activity of a block rat control team is the staging of an intensive eradication campaign through all buildings, yards, and lots in the block. This is done in a single operation. The steps of an eradication campaign are:

1. *Notification of block residents*—Residents are notified of a prospective campaign by means of placards which are posted in conspicuous places through the block and by notice cards which are distributed to all houses. The notices inform the residents of the intentions of the volunteer team and the mutual benefits which can be had through coöperation. They ask resident to clean up all exposed garbage, to leave their gates and outbuildings unlocked at a designated time and to confine their pets. At the same time they warn of the potential danger of the poison to unconfined pets and irresponsible children.

Requests to withhold poison from specified places are, of course, honored. Direct verbal permissions are sought whenever possible, but are not required. A city ordinance directing that properties shall be maintained free of rat infestation may be invoked in stubborn cases as needed.

2. *Distribution of poison bait*—Poison bait, generally ANTU at 3 per cent in finely ground corn,³ is distributed one or two days after notification or as soon as weather conditions permit. Each registered worker takes a bucket of prepared bait, as supplied to a local headquarters by the city crew, and proceeds through the block from the alley, placing small spoonful-sized piles in exposed and protected sites around all real or potential harborage, food sources, runways, and trails in yards and buildings. From 10 to 50 piles may be placed in an infested property, and from 10 to 40 pounds of bait is commonly used in an average sized block. Thoroughness is emphasized as fundamental to success; and places which cannot be entered are listed for further inspection and attention.

Prebaiting with unpoisoned food for several days or weeks before poisoning, as recommended by various workers, was tried experimentally in sample blocks in Baltimore. Its value, as demonstrated in these tests, did not appear sufficient to warrant the adoption of a prebaiting procedure which would greatly increase and complicate the work of the volunteer coöperators.

3. *Check-up of results*—When ANTU baits are used rats will die during the two days fol-

lowing treatment. Counts of dead rats are made during these two days, and all signs such as rat holes and fresh droppings obliterated on the second or third day, in preparation for further checks on survivors. Residents are asked to sweep up and discard all dead rats and all uneaten bait. A report on the operation is then prepared by the block captain and submitted to the city office.

4. *Follow-up*—Eradication campaigns are followed up immediately with special measures at all sites of persisting infestation. City crews assist in this work with burrow fumigation and traps. (This phase of the work is, at present, inadequately done as a result of poor reporting and technical difficulties.)

5. *Repeat campaigns*—Complete eradication is rarely achieved in a campaign. Thus, repeat treatments are usually indicated once a year and sometimes more often.

Experience with campaigns in the Baltimore program is still limited. The repetition of ANTU-corn campaigns at yearly intervals has been successful, but repeat campaigns at shorter intervals have given some poor results, apparently as a result of bait refusal. The present policy is, therefore, to use ANTU-corn in overall block campaigns once a year, and other measures, such as burrow fumigation, trapping and poisons with alternate poisons and baits, in interim treatments, as needed.

Sanitation Program

Community sanitation, particularly garbage disposal, is regarded as an integral part of rat control in the Baltimore program. Volunteer rat control teams usually take considerable interest in correcting insanitary conditions in their blocks. As an aid in this work one or two sanitary inspectors are assigned to the Rodent Control Division by the Health Department, and sanitary inspector authorizations are given to a limited number of volunteer leaders. More than a thousand notices and several dozen summonses have been handed out in connection with rat control programs during 1945 and the first six months of 1946. As a result of these activities thousands of regulation garbage containers have been installed in treated blocks and hundreds of "unsanitary conditions" eliminated.

Ratproofing Program

Householders are encouraged and instructed in methods of repairing breaks and closing openings in their houses as a means of protecting their homes, breaking up the rat ranges within the block, and delaying reinfestation.

ADMINISTRATION OF PROGRAM

A small office force and field force are maintained by the city for the purpose of: (1) handling requests and complaints, (2) organizing volunteer groups, (3) supervising control operations, (4) preparing the delivering baiting materials, (5) giving demonstrations and talks to volunteer groups, (6) coordinating field programs, and (7) conducting eradication work in unorganized blocks. A budget of \$44,000 served to run the program in 1945; the major items of expense were labor and baiting materials.

The coordination of volunteer programs is facilitated by a system of regional and district leaders. Following the pattern of Civilian Defense, the city is divided into ten districts, each placed under the direction of a volunteer "Chief Inspector." The subdivisions and the alignment of officers within a district vary according to the conditions and wishes of the local groups. District captains and their assistants do most of the work of organizing the coordinating block programs. A close cooperative arrangement is maintained between the city officials and the research departments of The Johns Hopkins University, where studies on rat ecology and rat control techniques are conducted.

RESULTS OBTAINED

The success of block eradication campaign and of the overall program may be evaluated on the basis of: (1) public reaction, and (2) measured changes in the rat populations.

Public Reaction

Public reaction often gives an errone-

ous impression of the actual results obtained. It is, however, a measure of the popularity and hence the "health" of the program. Enthusiasm is generally proportional to the number of dead rats recovered rather than the percentage killed and, therefore, is greatest in warm weather when more rats die in places where they are readily found. There is some loss in enthusiasm in repeat campaigns which give poor kills even when the workers recognize that the small recovery may reflect a reduced capital population. Conspicuous failures, as they occasionally occur through faulty technique, are quite damaging to volunteer morale.

Volunteer leaders, taught to expect a 90 per cent reduction, reported their reactions as follows during 1945: Good, 178; Fair, 65; Poor, 48.

Block residents who took no part in the program were questioned in one group of blocks a year after the first poisoning campaign. Their reactions on the success of the campaign were as follows: Good, 73; Fair, 9; Poor, 3.

Measured Results

Measurements of the success of poisoning campaigns were obtained by making detailed surveys in sample blocks before and shortly after treatment.⁴ A comparison of rat signs in these pre- and post-treatment surveys indicates that reductions of between 85 and 95 per cent are commonly obtained in residential blocks when the job is done thoroughly. Kills of from 50 to 80 per cent are encountered where the operators miss a few important yards or buildings, or where recent applications of poison have resulted in bait prejudices among local groups of rats. Heavy rains on the day of poisoning may result in a poor kill, and an inferior quality of corn has been responsible for some poor results during periods of grain shortage.

Periodic censuses following poisoning campaigns show that a decimated popu-

lation in a block will usually increase at a rate of between 2 and 6 per cent of the original population of the block per month.⁵ Thus a population reduced to 10 per cent of its original level requires from 15 to 44 months to recover. The average block reaches 58 per cent in one year and will approach complete recovery in 22 months. Populations reduced to 5 per cent or less of the original level often show retarded or delayed recoveries, so that the total period required for recovery is considerably prolonged.

With these reductions and rates of recovery it is clear that repeat campaigns at yearly intervals can hold a rat population well below its saturation level. Where successive campaigns serve to reduce the population to the same point (about 10 per cent of the original level) each year, the average population curve will describe a course like that shown in Figure 1, and the number of rats present will never exceed about 58 per cent of the original population. Should each successive campaign succeed in removing 90 per cent of the rats present, the population can well be forced down to a level from which recovery is very slow and irregular or is delayed for an indefinite period (E in

Figure 1). Special measures at such times may lead to complete extirpation. In one test block which was completely cleared of rats by persistent efforts, no rats reappeared for three years although neighboring blocks were moderately infested.⁵

Significance of Results

The value of control of the type here described is, of course, limited to the area treated and must be measured in terms of the local destructiveness of rats. Under most circumstances the destructive potentialities of a rat population are probably proportional to its size, and the benefits derived from a reduction campaign proportional to the reduction effected. Thus, in a block population under annual treatment, following the course shown in Figure 1, the total benefits may be appraised by measuring the area above the population line. In this case the benefits vary from 42 to 90 per cent and average 66 per cent throughout the year (C-D in Figure 1.) The greatest benefits may be realized by scheduling campaigns so that the lowest population levels coincide with the season of greatest local destructiveness or disease hazard, generally the summer.

FIGURE 1—Fluctuations of a hypothetical (average) rat population subjected once a year to a thorough eradication campaign. The reductions effected by poisoning (vertical declines) and the slopes of recovery (sloping inclines) are based on actual measurements made on experimental block population in Baltimore. The line A-B represents an average recovery rate; A-H and A-J represent the extremes encountered in measurements in 23 sample blocks.

LIMITATIONS AND HAZARDS

Baltimore's program of rat control in residential communities as described in this report has a number of limitations which should be considered.

As with any type of suppression program, benefits can be measured only in short-term values. A number of improvements are believed to have been made over other types of suppression campaigns, but any long-term benefits must necessarily rest on continued public support. A serious accident resulting from misuse of poison or a few outstanding failures could greatly injure volunteer morale and thereby disrupt the whole program. Furthermore, it is a common attribute of human beings to drop their enthusiasm as soon as an unfavorable situation has been alleviated and before it has been eliminated.

After a series of comparative field tests, ANTU is still the only raticide considered effective and safe for this type of program.⁴ ANTU is of little value against roof rats (*R. rattus*) which occur abundantly in many cities, particularly in the South. When properly used in Baltimore, ANTU gave excellent results against brown rats (*Rattus norvegicus*), but irregular usage has already led to a number of local complications and failures in repeat treatments. A widespread dissemination of ANTU to householders, now that all government restrictions have been lifted, might seriously reduce the effectiveness of ANTU campaigns against brown rats.

Hazards to humans and to pets seem to be relatively small in the type of program used in Baltimore. Every available source of information points to a high tolerance to ANTU by humans, but the potential dangers are still incompletely known. Ten children have been reported to have eaten ANTU baits since 1943; all but one had their stomachs emptied by stomach pump, and none showed any ill effects.

Cats, chickens, and rabbits are rel-

atively resistant to ANTU poisoning, but dogs succumb to doses of as little as 50 mg. per kg.⁶ Several dozen dogs, mostly vagrants, have been killed in the Baltimore program. This number is very small, however, when compared with the number of dogs exposed. Close coöperation between dog owners and poison crews minimizes the hazard to dogs, but occasional slips are hard to avoid.

The question of personal and property liability among volunteer workers poses a minor problem which in Baltimore is handled, as it was with air raid wardens, by assigning all responsibility to the volunteer.

SUMMARY

A procedure for rat control in residential communities has been developed in Baltimore, Md., on the basis of intensive local eradication campaigns repeated at appropriate intervals by volunteer residents under city direction. Four-fifths of the residential blocks of Baltimore have been treated one or more times in the eighteen months since the start of the full-fledged program in January, 1945.

All work is done on an areal unit basis, the square city block being the unit employed. ANTU in ground yellow corn is used as the standard poison bait. Community sanitation and ratproofing are encouraged in conjunction with the baiting campaigns.

Reductions of 85 to 95 per cent are generally obtained in well conducted block campaigns. Populations so decimated usually require from 15 to 44 months to recover to their original levels. Repeat campaigns once a year can thus hold a block population well below its original level and reduce the annual rat damage by about two-thirds.

A.D.A. Council Rules on Bone Meal and Flourine Products

The Council on Dental Therapeutics of the American Dental Association, Chicago, has recently ruled that bone meal preparations for the prevention of dental decay are not acceptable to the Council.

It is pointed out that during recent months there have appeared on the market a number of preparations containing powdered cattle bone, supplemented with vitamin D, for the treatment and prevention of dental caries. In view of the lack of evidence to show that they are effective for this purpose, preparations of bone meal for the treatment of dental caries are declared not acceptable for inclusion in Accepted Dental Remedies.

The Council has also considered the role of fluorine in dental caries with special reference to synthetic fluoride tablets. It is pointed out that the mechanism through which fluorine produces a lowered caries attack rate is not known. In the opinion of the Council there is no evidence that the protective mechanism, whatever it is, can be effective through fluoride-bearing water supplies in persons after they have reached the age when the teeth are fully formed. It also has not been demonstrated that

the ingestion of fluorine after the teeth are calcified will make the mechanism operative to arrest caries activity in man. They point out that, because of the great popular interest in the potential value of fluorine as an effective agent of caries control, there is ample opportunity for the exploitation of the public and of the professions through the sale of useless and even harmful preparations.

The Council has concluded with reference to many different tablet preparations containing some synthetic salt of fluorine and one or more vitamins, which recently have been offered that, though probably not dangerous in amounts recommended for daily consumption, fluoride added to diets already high in fluorine content or consumed in areas where water supplies contain significant concentrations of fluorine may constitute a health hazard. This possibility and the inconclusive nature of experimental evidence concerning their effectiveness render synthetic fluoride and fluoride-vitamin preparations for use in the treatment of dental caries not acceptable for inclusion in Accepted Dental Remedies at this time.

Determination of Filth and Extraneous Matter in Dairy Products^{*}

J. O. CLARKE, F.A.P.H.A.

Food and Drug Administration, Chicago, Ill.

FILTH and other extraneous matter may enter into dairy products through insanitary and careless practices on the farm, in transit from farm to manufacturing establishment, and in the manufacturing plant itself. Any filth found in a food is not only repugnant in itself, but also is indicative of insanitary and improper conditions of production. Filth such as cow manure, rodent hairs, flies and other insects, fragments of feathers, and dirt may be found in dairy products. When such filth is found, it demonstrates conclusively that the dairy product was produced under insanitary conditions, and the type of contamination gives a clue to the nature of the objectionable condition. For example, a fly leg in cheese shows that the cheese or its components were not protected from flies during their production.

Two distinct operations are involved in all methods for the determination of filth and extraneous matter in dairy products. First the filth or other extraneous matter must be separated from the food itself. It should be noted at this point that while present methods are limited to separation of only the insoluble components of the filth, we are actively engaged in developing methods for separation of the milk soluble components of manure or insects from dairy products. Second, the character or identity and the amount of the extraneous

matter must be determined by visual examination with or without the aid of microscopic techniques. Identification of the elements of filth requires experience and familiarity with the microscopic structure of hairs, insect particles, feathers, manure fragments, etc. The amount of filth may be measured by comparison with specimen sediment pads or the individual filth elements may be counted and the size measured.

It is rarely possible to separate completely the extraneous matter from the food substance itself. However, it is necessary that the separation be sufficiently complete to permit identification of the filth elements. There is no single method suitable for separating filth from all types of dairy products or even all samples of a given type of dairy product. For instance, filth in a sample of sweet cream can be removed by simple emulsification and filtration through a sediment disc. On the other hand, some samples of sour cream resist filtration to an extent requiring treatment of the sample by elaborate chemical methods in order to coax it through the sediment pad. Fresh milk usually can be filtered through a sediment pad with ease, but occasionally its physical condition is such that it becomes very difficult to filter.

Filth and sediment tests are a very useful tool both for the regulatory official and for the industry. However, it is important to note the limitations in interpreting the significance of such tests when negligible amounts of filth or

^{*} Presented before the Laboratory Section of the American Public Health Association at the Seventy-first Annual Meeting in Cleveland, O'ho, November 17, 1946

sediment are found. Such findings may merely indicate that efficient straining, filtering, or centrifugal clarification effectively removed the visible filth. Such devices, however, do not remedy the insanitary conditions responsible for the original contamination and cannot remove the soluble elements of filth.

Tests for filth and extraneous matter are most valuable tools for use in connection with sanitary inspections of dairy products manufacturing plants. During the inspection of a factory the inspector should not only make careful observations of the sanitary conditions of the plant itself, but he should employ field methods for making sediment tests on the milk or cream received by the plant from the producers. All too frequently even those dairy plants which are models of sanitation may accept and use milk or cream containing filth and extraneous matter.

MILK

The determination of filth and extraneous matter in milk provides a very valuable index to the quality of the milk not only to the inspector but also to the conscientious manufacturer. Such tests are simple and at the present time revealing. A negative test as previously pointed out may merely mean that the producer did a good job of filtering, but at the present time there is so high an incidence of positive tests in milk delivered for manufacturing purposes that the information furnished by such tests is very valuable. Sediment testing is no substitute for a comprehensive farm inspection program, but it does give a lead to the worst farms. Sediment testing by dairy plants should be performed systematically so that the milk from each producer is tested periodically. When dirty milk is revealed, it should be rejected on the spot and not used for production of dairy products for the market. The producer of rejected milk should be

visited by a representative of the dairy plant in an attempt to correct objectionable practices on the farm. If these efforts fail, the farmer should be denied a market for his milk.

The Food and Drug Administration performs sediment tests at the time of every inspection of dairy plants using milk as a raw material. Bottom-can samples consisting of one pint of milk are collected and passed through a conventional sediment disc. Since large amounts of dirt and filth are uncovered by bottom-can sampling, the test becomes more sensitive than the mixed-can sample test. While the amount of sediment obtained from a bottom-can sample will vary, depending on whether the can of milk has been shaken or stirred, it does, under most conditions of use, reflect the degree of contamination more accurately than the mixed-can sample. Of great importance also is the fact that the bottom-can sample provides an amount of extraneous material sufficient for microscopic identification of the filth present in the milk.

In performing sediment tests, inspectors of the Food and Drug Administration seek to test a cross-section of the milk being received by the dairy plant. The test pads are suitably mounted for transmittal to the laboratory for examination and to provide a permanent record. The quantity of sediment is estimated by comparing the test pads with a photographic strip which pictures sediment pads prepared from milk containing known amounts of sediment measured in milligrams. The amount of sediment is recorded as 0, 0.5 mg., 3.0 mg., 6.0 mg., and 12.0 mg. In practice an instrument is used which removes approximately one pint of milk on the upstroke and filters it through the sediment pad on the downstroke. The Food and Drug Administration studies the sediment pads in connection with the inspector's report of sanitary conditions in the dairy plant. Regu-

latory action under the Food, Drug, and Cosmetic Act follows when dirty milk is being used or the plant is operating under insanitary conditions which may contaminate the product with filth.

During the period from March through September, 1946, inspectors of the Food and Drug Administration operating in the mid-continental part of the United States made tests on 272 lots of milk delivered to cheese factories. Forty to 175 cans of milk were sampled in each test, the average being 69 cans; 19,811 cans were examined in all.

The results of each test were recorded as the percentage of the milk containing 0. 0.5 mg., 3.0 mg., 6.0 mg., and 12.0 mg. of sediment. We are confining our discussion of these tests to the milk showing 3.0 mg., 6.0 mg., and 12.0 mg. of sediment since this amount represents a significant quantity of filth and extraneous material. A cross-section of the sediment pads from each test was examined microscopically in the laboratory and the identity of the filth was determined. Generally the sediment consisted of cow manure, various kinds of hair, insects and insect parts, feather fragments, dirt, rust, metal particles, etc.

Table 1 summarizes the data obtained from the 272 inspections. The table lists the number of these inspections broken down in terms of the percentage of such filthy milk in the total cans examined at each inspection. For example, the column under the heading 3.0 mg. shows that none of the 272 tests revealed a complete absence of 3.0 mg. milk, that 26 of the tests yielded from 1 per cent to 9 per cent of 3.0 mg. milk, and that 42 of the tests yielded from 10 per cent to 19 per cent, etc. Similar data are shown for the 6.0 mg. and 12.0 mg. milk.

Table 1 reveals the significant fact that 199 inspections out of the 272 (or 73 per cent of the total) showed some milk yielding 12.0 mg. pads when tested by the bottom-can sampling method. It

TABLE 1
Sanitary Classification of Milk Delivered to Cheese Factories, Spring and Summer, 1946

<i>A. As to incidence of 3 mg pads</i>		
<i>Percentage of Pads Among Total Cans Tested</i>		<i>Number of Inspections</i>
No 3 mg. pads at all		0
1% through 9% 3 mg. pads		26
10% " 19% 3 mg pads		42
20% " 29% 3 mg pads		78
30% " 39% 3 mg pads		72
40% " 49% 3 mg pads		41
50% or more 3 mg pads		13
<i>B. As to incidence of 6 mg pads</i>		
No 6 mg pads at all		26
1% through 9% 6 mg pads		127
10% " 19% 6 mg pads		78
20% " 29% 6 mg pads		21
30% " 39% 6 mg pads		13
40% " 49% 6 mg pads		5
50% or more 6 mg pads		2
<i>C. As to incidence of 12 mg pads</i>		
No 12 mg pads at all		73
1% through 9% 12 mg pads		148
10% " 19% 12 mg pads		36
20% " 29% 12 mg pads		13
30% " 39% 12 mg pads		0
40% " 49% 12 mg pads		2
50% or more 12 mg pads		0

is interesting to note that of the grand total of 19,811 cans of milk examined, 28 per cent showed sediment to the extent of 3.0 mg., 11 per cent to the extent of 6.0 mg., and 6 per cent to the extent of 12.0 mg.

To furnish information about individual tests, the results of a number of representative tests showing a minimum amount of sediment, average sediment, and heavy sediment have been detailed in Table 2. These tests were selected

TABLE 2
Typical Tests on Cheese Milk

<i>Date of Inspection</i>	<i>No Cans Tested</i>	<i>Per cent of Milk Showing Pads</i>		
		<i>3.0 mg</i>	<i>6.0 mg.</i>	<i>12.0 mg.</i>
4/17/46	100	12	1	0

from the 272 described in Table 1 in such a manner that they present a picture approximately the same as the results of all of the 272 tests.

OTHER DAIRY PRODUCTS

While sediment tests on milk are made by a very simple technique not involving chemical treatment of the sample, this simple procedure is not generally applicable to other dairy products.

The methods for most other dairy products involve chemical treatment of the sample to facilitate filtration through a sediment pad or filter paper. The methods used on cream for butter making can be performed in the field, but require the inspector to carry with him chemical reagents and equipment for treating the sample. A vacuum pump is necessary. A small proportion of cream samples can be filtered through a sediment pad merely by diluting the cream with hot water. After treatment with hot water, even old cream can be filtered through a coarser medium, but a filtering medium permitting filtration in this manner will not retain the fine particles of sediment. It does retain significant filth elements such as insect parts, and some rodent hairs. Generally, to facilitate filtration of cream through pads, caustic soda is used to neutralize the excess acidity and sodium metaphosphate solution to assist in emulsification. After such treatment the liquid usually will pass through the conventional sediment pad.

Some creams, particularly those containing a considerable amount of mold, will not filter even after treatment with sodium hydroxide and sodium metaphosphate solution. With such creams it is necessary to sacrifice the complete recovery of filth by filtering through a coarser medium or separating the heavy filth by drawing off a part of the material from a separatory funnel and treatment of the remainder by entrapment in a Wildman trap. The Wildman trap

is used for the detection of filth in a wide variety of substances. It consists of a one or two liter Erlenmeyer flask fitted with a rubber stopper attached to the end of a rod which is inserted bottom side up into the flask. When the rubber stopper is brought to the neck of the flask it forms a seal. The material in the flask suspended in water or other liquids is thoroughly shaken with a small amount of gasoline or other oily material. The particles of gasoline attach themselves to the filth substances and bring them to the top of the liquid. The gasoline layer together with a small part of the aqueous layer is poured off after trapping in the neck and is filtered. The residue of filth and extraneous matter on the filter is then available for microscopic examination.

Smaller amounts of filth and extraneous matter are usually found in cream than in the milk from which it is separated, since there is a tendency for elements of filth to follow the skim milk rather than the cream through the separator. However, since cream is held longer on the farm and is manipulated as it passes through the cream station to the creamery, it is particularly subject to contamination after separation. The microscopic examination of the sediment pad is most important when dealing with cream. Microscopic examination of cream pads sometimes reveals small maggots resulting from fly contamination, as well as other filth elements.

Recently developed methods are now available for separation of filth and extraneous matter from a number of finished dairy products such as cheese, dried milk, evaporated milk, and butter. Two general principals are involved in these methods. The first class of methods embraces products which can be emulsified by chemical treatment with or without digestion with pancreatin. The emulsified sample for quantitative estimation of filth is filtered through

paper. The second class of methods involves sedimentation and the use of the Wildman trap described above. It should be reemphasized that there is no universal method for all dairy products and diversified methods are frequently applied to the same type of dairy product. The method of choice for a particular sample is the one which minimizes the damage to the filth present and which results in near quantitative recovery of the filth. At times these two objectives are not completely compatible, and it becomes necessary either to sacrifice complete recovery or to endanger the filth elements present.

The separation of filth or extraneous matter from finished dairy products is futile unless the identity of the elements of filth is established by microscopic examination. While this phase of the determination is also important in raw materials such as milk and cream, it is fundamental to proper interpretation of filth analyses on finished products. When large amounts and impressive types of filth are found in dairy products the determination speaks for itself and there is little need for additional evidence to support the conclusion that the product is filthy. However, it is more usual that the sample reveals very small amounts of filth, since practically all dairy products manufacturers strain or filter their raw material, and in these circumstances it is valuable to use additional data in interpreting the results. In interpreting the significance of a filth analysis, we should study not only the results on the particular sample involved, but all other samples from the same source together with sediment tests of the raw material and the report of the sanitary inspection of the place of manufacture.

Details of methods of analysis have not been given in the above discussion since many of the methods discussed have been published in the book of

Methods of the Association of Official Agricultural Chemists. These methods will also be published in the forthcoming edition of the American Public Health Association Methods.

The Food and Drug Administration has extensively used the methods described above in the enforcement of the Food and Drugs Act. The use of these methods in connection with factory investigations has furnished evidence to support an extensive regulatory program. Many seizures, prosecutions, and injunctions based on the application of sediment tests to both raw materials and finished products have been brought to a successful conclusion. In presenting such evidence to the courts, it is frequently valuable to prepare exhibits of filthy substances found in the food for presentation to the court. Milk and cream sediment pads are particularly valuable exhibits.

SUMMARY

1. Filth and extraneous matter in milk can be determined easily in the field, and at the present time such tests are widely used both by the industry and regulatory officials on milk for use in manufactured products.
2. Two hundred and seventy-two recent tests performed by inspectors of the Food and Drug Administration show that considerable quantities of milk containing large amounts of filth are received by cheese factories.
3. Sediment test methods for cream used in butter making are available for use in the field and in the laboratory.
4. Methods have been developed for the determination of filth and extraneous matter in cheese, evaporated milk, skim milk powder, etc. These are laboratory methods designed for use on finished dairy products.
5. The microscopic identification of filth elements is a very important part of any determination of filth and extraneous matter in dairy products.

The Medical Social Worker in a County Health Department

A Coöperative Plan Between a Health and Welfare Department

JESS B. SPIELHOLZ, M.D., AND IVA VAL BRAKEL

*Health Officer, Bremerton-Kitsap County Department of Public Health,
Bremerton, Wash.; and Supervisor of Social Services, Kitsap County
Welfare Department, Bremerton, Wash.*

OFFICIAL health and welfare departments frequently face mutual problems and responsibilities. Their recognition and an approach to their solution by utilizing the combined abilities and interests of the professionally trained personnel of both organizations would seem to be a desirable way of bringing increased service to the community. This is especially true in applying the services of medical social workers, whose contribution to the success of health department programs is just beginning to be appreciated. We propose to tell how, in one county, coöperative functional planning has resulted in a better working relationship and greater accomplishment.

DESCRIPTIVE

Kitsap County, in the State of Washington, covers an area of 394 square miles bordering on Puget Sound. Although there is some fishing, lumbering, and dairy farming, the economic life of this area centers around the Puget Sound Naval Base, a major installation located in Bremerton, the largest city in the county. As a result of war activities, the population of the county rose rapidly from the 1940 census of 35,000 to the present estimate of 160,000. Within Bremerton are concentrated at least 75,000 persons, a growth

from 15,000. This population is predominantly white except for about 5,000 Negroes and 500 Indians; it represents an influx from almost every part of the country.

THE HEALTH DEPARTMENT

The Health Department, functioning jointly for both city and county, was established as a full-time unit in 1941. Since 1943 it has been housed in the Franklin D. Roosevelt Memorial Hospital in Bremerton, a community hospital built with Lanham Act Funds and sponsored by the County Board of Commissioners. Because of its intimate physical relationship with the hospital, planned from the very beginning, the Health Department enjoys adequate facilities including use of the laboratory and x-ray equipment.

The Division of Sanitation enforces city and county regulations, including milk and restaurant codes based on U. S. Public Health Service standard codes, as well as adequate sewage and plumbing ordinances. It supervises sanitation of schools, houses of refuge, and convalescent homes.

The Division of Nursing conducts a generalized public health nursing program, including some bedside nursing. This was instituted in 1943 to meet some of the needs of an overcrowded

population and a relative shortage of practising physicians and nurses.

Regular tuberculosis, venereal disease, and orthopedic clinics are conducted at the Health Department. Immunization clinics are held periodically throughout the county, as are a few "mother-nurse" conference groups, in limited areas.

THE WELFARE DEPARTMENT

The State Department of Public Welfare was created by a Legislative Act in 1935. It is responsible for administering and supervising all programs through local county welfare departments. The Divisions for Children, Old Age Assistance, Assistance for the Blind, and General Assistance were established by law. The medical care program thus far has not been separately established by law.

County welfare departments are responsible for administering the total program in their respective communities. The Kitsap County Welfare Department functions under an Administrator with a staff of 17 professional and 7 clerical workers. It is the only county in the State of Washington which has medical-social workers on the staff. The medical-social work program as it functions with the Health Department is also unique.

Until January, 1943, the local health department was administratively part of the Welfare Department. This involved chiefly budgetary control and accounting practices. Tuberculosis hospitalization was also a Welfare Department responsibility. As a result of acts of the State Legislature, the two departments became completely separated and tuberculosis control and hospitalization was transferred to the Health Department. Medical care of relief recipients continues to be a Welfare Department program.

A medical-social worker was assigned to the Kitsap County Welfare Depart-

ment in December, 1943, to work with the medical care program. Her first assignment included development of medical-social service within the community, hospital admissions, and nursing home placements. Early in 1944, the County Public Health Director asked that medical case work services be made available to female patients of the venereal disease clinic and to tuberculosis patients.

In the early planning of this program it was recognized that medical case work service to such special groups, given by a welfare worker in a Health Department clinic setting, gave opportunity for a fresh method of approach. But it was agreed that continued service would depend upon the need for case work services evidenced by the patients as well as upon the recognition of the value of such service by the Health Department workers involved. Consultation with a medical-social worker was to be on a selective referral basis. Although the interests of the Health and Welfare Departments touch at many points, the chief areas of function of the medical-social worker in relation to the Health Department program have been centered about tuberculosis, venereal disease control, and orthopedic services.

VENEREAL DISEASE CONTROL

Two clinics a week are held at the Health Department offices for the diagnosis and treatment of venereal diseases. Patients come in through contact investigation, by direct application, upon referral of private physicians, and through the activities of public health nurses. There is no charge.

The venereal disease patients are seen by a medical-social worker after their clinic visit in a private interviewing room near the examination rooms. Facilities for privacy are adequate and the patient is given any length of time he wishes to discuss the problem involved. In the venereal disease clinic it

has been the practice to see women patients generally in the younger age group; that is, under the age of 25 years. Referrals are made by the physician or the clinic supervisor of nurses who has responsibility for interviewing patients and recording medical history. The majority of the group have been found to have problems with which they desire medical case work assistance and are carried on a case work basis as long as a need seems indicated.

Experience in the venereal disease clinic has shown invaluable opportunities for helping the patient confronted with the adjustment involved in venereal disease and its treatment. The patients showed varying degrees of guilt, and have considered it a moral problem in many instances, with a tendency toward self-blame. The emotional element often has been so intense that, without case work services, there might have been serious personality conflicts.

The majority of the 87 patients seen were comparatively new to the community and had come for wartime employment. Financial problems were almost nonexistent. While some of the group were unmarried, more were married, divorced, or separated. Of the group that was married, most had husbands in the service. Few housewives or students were represented, most of the girls being employed as waitresses or in the Puget Sound Navy Yard as war workers. Approximately one-fourth of the group had an eighth grade education or less. Thirteen were high school graduates and only three had any collegiate training. The largest number was concentrated in the age group between 19 and 24 years, although the age range was from 13 to 55 years. Fewer than one-fourth of the patients were of other than the white race. Most were from the mid-western states and had come from rural areas. The paramount problem centered around anxiety and guilt feelings related to their venereal

infection. As a group, they did not have meaningful family relationships and generally showed emotional immaturity.

In analyzing case work contributions, it is felt that the patients on a whole needed help. They seemed poorly prepared, however, either by life or experience to use any help. Promiscuity and sophistication served as a protection hard to break through. In establishing a meaningful relationship, the case worker has to meet the requests for tangible help and prove to the patient an interest in him as a person. It is believed that case work treatment cannot change to a marked degree the underlying conflicts in the patient, but by meeting dependency needs, accepting him as an individual, and giving support to his ego, he can be helped to function with less difficulty in his relationships with other people.

TUBERCULOSIS CONTROL

A chest clinic for the diagnosis and treatment of tuberculosis is held once a week at the offices of the Health Department. Medical services are given by a tuberculosis consultant. Patients and contacts are referred by private physicians, public health nurses, and as a result of an extensive miniature chest x-ray survey conducted jointly by the Health Department and the Tuberculosis League. In addition, a large proportion of the chest x-rays taken by private physicians are referred to the consultant for interpretation. The county maintains a 50 bed tuberculosis sanatorium under the administration of the Health Officer.

Each patient who is diagnosed as having active tuberculosis is referred to the medical social worker. This affords the patient an opportunity to express his feelings concerning the physician's diagnosis and recommendations. Frequently the patient is so upset emotionally that he finds it difficult to accept the treatment plan. He may resist

treatment for many reasons, but particularly because of concern about responsibilities for his family.

The medical-social worker attempts to relieve him of some of the anxiety and encourages him to talk about his attitude toward his illness so that she may determine the factors which to him appear paramount. If it is evident that the patient is confused in the medical interpretation given by the physician, the social worker usually requests the public health nurse or the physician to talk further with him to clarify his thinking.

The medical-social worker uses the first interview to explain in detail the services available for his care. She learns something of his financial ability to meet the medical needs for himself and also to provide for his family. It is always carefully explained to the patient that there are resources to meet his needs. When he leaves her office he has all the assurance that adequate assistance is available. If sanatorium care is indicated, she prepares him for his experience there, explaining visiting hours, what he will need in clothing, mentioning the occupational therapy and recreational facilities.

Financial planning with the patient is important, since the patients are accepted as free, part-pay, or private patients for sanatorium care. The problems confronting the tuberculous patient are much the same as those confronting any patient in need of long care away from the home. Needs presented often include foster home placement of children, or some form of public assistance for dependents.

Those patients showing a need for continued case work services are seen in the County Sanatorium by the same worker who sees them in clinic. She attempts to obtain sufficient information from the patient and other members of his family to get a rather complete picture of the patient as a person. Any

social problems which are revealed in securing the social study, particularly those that may aggravate the patient's condition, are alleviated as far as possible. In addition, she works with the patient's family to give them understanding regarding the patient's anxiety, and explains the important part that the family's attitude plays in his recovery. The medical-social worker's goal is to give as much supportive assistance as possible in an effort to help the patient make mental and emotional adjustments, thereby hastening his recovery.

To effect continuity in the treatment plan, the social worker shares with the medical and nursing staff the social problems which are a concern to the patient and his progress in social adjustment.

Lines of responsibility have been fairly well delineated. The public health nurse assumes responsibility when the major problem is health, such as contact follow-up and case finding. The medical-social worker offers case work services to the patients in the clinic, the home and in the sanatorium.

ORTHOPEDIC SERVICES

In April, 1941, service for crippled children was transferred from the State Department of Social Security to the State Department of Health with the understanding that the county welfare departments would do the social studies for the health departments. The State Department of Health has been conducting diagnostic clinics and providing for orthopedic care for certain children coming under the Crippled Children's Program. These clinics have been held several times a year in Seattle.

After the child has been examined by an orthopedic physician at a diagnostic clinic and treatment is recommended, the County Health Officer is notified by the State Department of Health of those children who are in need of treatment. A medical-social worker then

makes a social study based on information secured during a home visit. This is forwarded to the medical-social worker in the State Department of Health. This material is used by her in case work services with the child during his hospitalization period. After the child returns home, the medical-social worker and public health nurse continue working with him and his family in an effort to assist with any medical-social problems or nursing problems relating to the child's orthopedic condition.

Within the past few months an orthopedic clinic has been established in the County Health Department through the joint coöperation of the Health Department, the local chapter of the Poliomyelitis Foundation, and the County Medical Society. Consultant orthopedists from Seattle visit this clinic. All age groups are seen. Patients under 21 coming under the Crippled Children's Program and cases of poliomyelitis are seen free of charge. Private patients are also referred by practising physicians on a private fee-for-service basis. The Medical Director has requested the services of a medical-social worker in this clinic.

CHILD HEALTH

Mutual problems within the field of child health arise in connection with examination for placement in foster homes and supervision of the sanitation of these homes. The services of the Health Department sanitarians are available at the request of the social worker in investigating the environment before placement of these children.

ADMINISTRATION

Programs involving joint action are planned jointly by the administrators of the two departments or by their designated associates. Thought is given at the very beginning of the planning of any new program to the clarification of any overlapping administrative respon-

sibility. The function of the medical-social worker is carefully delineated. From there on supervision of the worker is provided by the Welfare Department supervisor. At the same time, the worker, while she participates in the joint program, has a definite responsibility to the Health Department director for medical interpretation in the individual case. She represents the Health Department to the patient until such time as a problem indicating Welfare Department responsibility enters into the picture. The patient or his family is seen by the case worker at the Health Department offices or the sanatorium.

An active program of staff education has been necessary in order to correlate the activities of the Welfare and Health Departments. Joint staff conferences of nurses, sanitarians, and medical-social workers have been found effective. Reciprocal orientation of new staff members of each department to the activities of the other has now become a routine procedure. The working relationship of the individual public health nurse and medical-social worker has been considerably strengthened so that each now avails herself more frequently of the services of the other.

The Health Department, which maintains student nurse affiliation, has included as part of the experience of the student nurse the various aspects of this interrelationship between the two departments, both through formal seminars with Welfare Department supervisors and by direct observation and participation. A medical-social worker has been asked to give a one hour class for each group of students, showing the working relationship between the public health nurse and the medical-social worker in the public health clinic. These classes have proved very interesting and informative for us and we hope for the student nurses. These students

come to the class oriented in the understanding of the function of the medical-social worker in a hospital. The problem is one of relating this information to the work in the public health clinic. It is sometimes a little difficult at first for them to visualize the medical-social worker attached to the County Welfare Department, giving case work services outside of the hospital. Brief illustrative case material has been helpful in making the interpretation to the student nurses and the hour has usually ended with the nurses thinking of patients in their own field work case load who might profit by the medical case work service.

PUBLIC RELATIONSHIP AND ATTITUDE

The services of the social worker have been accepted as part of the services offered by the Health Department to the patient. This was not always true when the worker was introduced as a member of the Welfare Department and interviewing was done at the Welfare Department offices. The medical profession, too, is accepting the role of the medical-social worker. This is especially true in connection with problems presented by tuberculosis control. It is becoming progressively more apparent, however, in other fields of medical interests. For example, in drawing up a plan for a definite understanding between the Medical Society and the Health Department in relation to the activities of the venereal disease clinic, the medical-social worker was included.

CONCLUSION

The joint program was initiated on an experimental basis over two years ago, and results have been so gratifying that it is now fully accepted by both departments. They are deriving mutual benefit and satisfaction in meeting social and medical problems in the community together.

The County Welfare Department realizes that this joint sharing of community responsibility with the Health Department has had definite value in developing its medical-social program. It has provided an opportunity for its medical-social workers to work directly with the County Health Director and have the benefit of his medical supervision in the venereal disease clinic, and with the chest consultant in the sanatorium and tuberculosis clinic. This has broadened their experience and assisted in their professional development. Thus the medical-social worker and the nursing staff have a much deeper appreciation and respect for each other's profession. This could not have been accomplished except through day by day working relationship, each making an effort to understand the function of the other.

A review of the joint program leads to the conclusion that both departments have gained by the close working relationship. The Health Department has had placed at its disposal the services of trained medical case workers and has thereby been able to incorporate into its program consideration of the social side of disease and of public health problems.

Equally important, it has drawn the staffs of the two departments more closely together so that each has a better understanding of what the other professional worker is trying to do. Coöperative solution of joint problems is no longer a theoretical ideal. Through closer working with the medical staff, the social worker is better able to appreciate the social needs in relationship to the medical needs and, because referral to her is immediate, to take immediate steps to meet these needs. The Health Department and the medical profession are coming to recognize the case worker as a person whose functions go far beyond financial clearance.

Health and Social Statistics for the City*

HALBERT L. DUNN, M.D., PH.D., F.A.P.H.A.

*Chief, National Office of Vital Statistics, U. S. Public Health Service,
Federal Security Agency, Washington, D. C.*

FOR the last two years, Esther Wright of the staff of the National Office of Vital Statistics has been devoting full time to the program of small area statistics in cities. The plan of operation has been to assist in every way possible Howard Whipple Green of Cleveland, W. Thurber Fales of Baltimore, and Leon Truesdell of the Bureau of the Census to reduce to writing and graphic form their extensive "know-how" in this subject. This should make it possible for other workers to benefit from their experience and to carry on this important activity in the other large cities of the country. With the reissuance of the *Census Tract Manual*, which I understand will soon be available, and with the completion of various other materials and exhibits, this phase of the program will soon be an accomplished fact.

During these last two years, I have been questioned many times why vital statistics was interested in this work. "What has it got to do with vital registration?" "How will it aid the tuberculosis program?" "Why are vital statistics consultants surveying the present use of census tracts in various cities?" "Why are they approaching businessmen concerning their need for census tract data?"

The answer to all such questions is a very simple one. We are interested in people. By this, I do not mean an interest focused primarily on people as cases of tuberculosis or syphilis or heart disease; or an interest in families as social welfare problems or as potential trade customers; or an interest in youth as juvenile delinquents. What is meant is that we have an interest in people and in families as such—in their characteristics—in the way they are distributed throughout the city. We realize that the vital statistics we publish will always have a limited usefulness and significance unless they are related closely to the way people live, to the kind of jobs they have, and to the problems they face.

A basic statistical knowledge concerning the people themselves should underlie all subject-matter programs. Yet in many, many instances, programs are devised which are faulty because of insufficient knowledge concerning the people at whom they are directed. For example, schools have sometimes been placed where there are not enough children to use them; cities have occasionally laid out development plans without an awareness of the degree of population growth to be anticipated; businesses have charted their future courses at times without taking into account the supply of workers which they need or the potential customer market. Even world-wide problems such as those involving labor supply and job opportuni-

* Presented before the Vital Statistics Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946.

ties, food resources, immigration controls, and numerous others have had to be acted upon without sufficient knowledge of population factors. Perhaps a hopeful sign for the future is the recent clear-cut recognition by the Social and Economic Council of the United Nations that a Population Commission is necessary to cope with just such deficiencies.

Up to the present time, the primary national interests in demographic or population analysis have centered in universities or foundation supported organizations. Scripps, Princeton, Milbank, Hopkins—these are the names that come to mind. The Bureau of the Census has, of necessity, devoted most of its energies to the obtaining of population data rather than to the analysis of these data. National, state, and city planning commissions, though usually inadequately financed, have made a beginning. Little has been done by the state health departments or vital statistics units in the field of population analysis. A few counties have shown interest.

When it comes to cities, however, all of us recognize two in particular which have a clear-cut focus of population data. They are Cleveland and Baltimore. It is due to the efforts of Howard Whipple Green and W. Thurber Fales that we are primarily indebted for the brilliant pioneer work which has set examples of what can be done. In addition, Birmingham, Chicago, Cincinnati, Detroit, Los Angeles, Milwaukee, New York, Pittsburgh, and several other cities have made considerable progress along these lines.

The technique of creating a focus for population facts in large cities has been simplified by the existence of population data tabulated in census tracts. Census tracts are small areas into which large cities are divided. Data collected by the Bureau of the Census are tabulated by these small areas. They have definite and permanent boundaries.

Each tract includes a population of between 3,000 and 6,000. It is fairly homogeneous with respect to race, nativity, economic status, and general living conditions.

In general, all population items were tabulated by race and nativity and housing items, by occupancy and tenure and color of occupants, wherever applicable. This is true of both published and unpublished tabulations. Tabulated but unpublished items for census tracts include: nativity of minor races, school attendance, industry groups of employed workers 14 years old and over, exterior material of residential structures, number of rooms of dwelling units, lighting equipment, cooking fuel, water supply, bath, tub or shower, furniture, and rent.

In 1940, census tract data were made available for 60 of the larger cities of the country. The existence of population tabulations by census tracts means that a reasonably complete knowledge of the people and families in a large city can be obtained by summarizing and coordinating all such facts for a few score census tracts and by keeping these facts *up to date*. Vital statistics is an important part of this task since the current allocation to these tracts of births, deaths, marriages, and divorces is needed to revise the once-in-ten-year census population picture throughout the interim census period.

City health departments, like other city agencies, have two basic uses of census tract data: (1) health statistics compiled on a census tract basis serve to show the geographical distribution of health problems; and (2) health statistics compiled on a census tract basis may be related to other social and economic factors available by census tract. Both of these uses are sometimes expressed in the larger health area units by reassembling the census tract data.

In recent years, public health administrators generally have adopted the philosophy that public health programs

are best administered in large cities through a neighborhood health center plan. These health centers are usually the administrative units of health areas. Generally, a health center area is designed to include a population of approximately 25,000. The health area boundaries should be contiguous with census tract boundaries. Data may be tabulated by tracts and data summarized by health areas.

Homogeneity in population characteristics is difficult to maintain in a population grouping of 25,000 or more persons. It may frequently happen that a particular health problem will exist in only one small section of a health area or it may happen that a health problem will arise in two contiguous census tracts which are in different health areas and thus require the coöperation of the two health officers concerned. Finally, it should be noted that population and housing data can be compiled for health areas only if the health area represents combinations of census tracts for which census data are available.

A second problem of administration lies in obtaining citizen participation in health programs. It is very difficult to get all the city interested in a problem localized in only one section of the city. It is relatively easy, however, to obtain community interest and action on problems affecting each small community. This, of course, is one of the reasons for establishing community health centers, but it must be remembered that it is possible to compile all the pertinent data for the community only if the community is a grouping of census tracts. It should also be emphasized that a health area embracing a small number of census tracts is much more apt to have a fairly homogeneous population with common interests than a health area drawn with no reference to base population data.

Spotting births, deaths, communi-

cable disease cases, and nurses' visits on a tract map shows the health administrator where his "business" is. Mothers' classes should be organized in areas where births are most frequent. Special classes and special preventive measures should be taken in areas where stillbirths and infant deaths predominate. Well baby clinics should be located in the areas where the babies live. Venereal disease and tuberculosis clinics should be located in the areas where venereal disease and tuberculosis cases are clustered most. Similarly, public health education programs on venereal disease and tuberculosis should be stressed in these areas. Special preventive measures should be taken in areas where certain other communicable diseases occur. Accident prevention programs should be stressed in areas where accidents occur and areas where persons who are involved in accidents reside. Out-patient hospital clinics should be located in areas where the people who use them reside. Nurses' areas should be designed according to the distribution of demand for nurses' services. Housing inspections and inspections of food establishments are presumably made on a city-wide basis. It is a good idea to design inspectors' areas by census tracts and to keep inspection records on this basis. "Problem areas" may be easily spotted and special attention can be given these areas.

There are other possible uses but each should be studied carefully. Prenatal clinics, for example, might be established in areas where births predominate. Certainly a study of population trends and an analysis of births by residence should be one factor in the considerations of selecting sites for such clinics. On the other hand, it may be necessary to install such clinics where hospital facilities already exist. Similarly, facilities for the care of crippled children should be established where the greatest number of persons needing such

care live, but the location of existing facilities will probably be the final determining factor.

As important as it is to have information on the geographic distribution of health problems, it is equally important to be able to relate health phenomena with other social and economic conditions. This can be done by analyzing health data on a census tract basis. As previously stated, census tracts are designed to include relatively homogeneous populations of approximately 5,000 persons. A wealth of data on age, race, nativity, sex, education, employment, housing conditions, and economic status are available for each tract from the federal census. Locally collected data on housing, recreation, juvenile delinquency, school attendance, and so on may also be compiled on a census tract basis. It is a truism that two widely separated tracts having the same living conditions represent more of a community of interest than two contiguous tracts widely different in economic status.

The Committee on Census Enumeration Areas of the American Statistical Association has illustrated as scientific exhibits two of the uses of tabulations of data by census tract.

The first exhibit demonstrates the low ratio of toxoid inoculations to births in Baltimore. By means of this knowledge, the city health department was able to concentrate its efforts on an intensive immunization campaign. The second exhibit sets forth the relation between health and economic factors in Cleveland.

One more use of census tracts should be noted. Census tracts provide an excellent base for sampling. Census tract data also provide sufficiently detailed information for small population groups to form a basis for selecting small areas having specified characteristics for intensive study.

It is not necessary to make frequent

elaborate tabulations by census tract. In fact, such a procedure should be avoided since tract tabulations might then become an unnecessary burden on the health department and eventually be dropped altogether for this reason. Certain basic records should be routinely coded by tracts. These include births, deaths, stillbirths, communicable disease cases, nurses' visits, and residence of persons attending various clinics.

Monthly tabulations of total births, deaths, stillbirths, and communicable disease cases should be made by tracts but it is probably unnecessary to make any detailed tabulations this frequently. More detailed tabulations should be made annually. These might include births by race, total stillbirths by race, total deaths by race and age (5 age groups only). Deaths from selected causes should also be tabulated by race, sex, and age. These causes should include the ten leading causes and any others in which there is special interest. A tentative suggestive list includes tuberculosis, pneumonia, diseases of the circulatory system, cancer, diabetes, nephritis, cerebral hemorrhage, accidents, meningococcus meningitis, poliomyelitis, rheumatic fever, maternal deaths, and, of course, infant deaths. Reported cases of certain communicable diseases should also be tabulated by race, age, and sex. Nurses' visits should be tabulated by type of case and type of service. Clinic visits should also be available by type of case and race. More detailed tabulations than these should be made only for special studies. It is important, however, that all records which might be analyzed by tracts should be routinely coded by tract. This coding operation takes very little time if done regularly, and punching tract identification along with other information also adds little to the regular work.

Before closing, I should like to point out that the staff of the National Office

of Vital Statistics fully recognizes the fact that a focus of population statistics in the large city can be created in other types of organizations than in city health departments. There is no doubt in my own mind, however, that the best focus for such a population register will usually be found to be the vital statistics section of the city health department. This conclusion is based primarily on the consideration that such a population focus needs: (1) an office staff with knowledge and skills in indexing, coding, and statistical analysis, (2) a budget sufficient to furnish freely the population statistical services to organizations needing them, and (3) an

adaptation of the current flow of vital records for the purpose of keeping the population register up to date. Likewise, it is my opinion that both the health and vital statistics responsibilities of the city health office can be met more adequately by such a development.

The future program of the National Office of Vital Statistics includes promotion of the establishment of population registers in all of the large cities of the country. In coöperation with the Bureau of the Census, the state health offices, and other interested organizations and individuals, we hope to implement this program through training and demonstration projects.

Public Health Coöperation in Student Nurse Recruitment Program

The Student Nurse Recruitment Program for enrolling 45,000 student nurses in the nation's 1,300 schools of nursing in 1947, being conducted by the American Hospital Association, the Advertising Council, Inc., the American Red Cross, and national nursing organizations, was briefly outlined in the *May Journal*, page 630.

The campaign stresses positive aspects of nursing—the hundreds of interesting jobs open in hospitals and in non-hospital fields, the higher pay and shorter hours now generally prevailing for nurses, the high standards of education offered at low cost, the value of nurse training as preparation for a career, marriage and family and community life, and the high respect in which the nursing profession is held by the community.

Programs in high schools, information centers for prospective student nurses, conducted tours of the local hospital or school of nursing for high school students, talks by nurses recruitment officials before civic, social, and business

groups are planned as part of the local recruitment programs.

Ways in which local public health groups can assist in recruiting student nurses include sponsorship of advertisements in newspapers or spot announcements over local radio stations in coöperation with a local hospital, school of nursing, or nurse recruitment committee. Proofs of advertising mats prepared by the Advertising Council, Inc., have been sent to schools of nursing. In coöperation with nurse recruitment officials, local public health groups might prepare a brochure or booklet on nursing, assist in arranging nursing education meetings of various clubs and organizations and high school groups, operate an information booth on nursing in a department store or some other central place.

Public health officials interested in assisting the 1947 Student Nurse Recruitment Program are urged to get in touch with nursing schools and hospitals for further information about local nursing needs and recruitment efforts.

WHAT IS HEALTH EDUCATION?

HEALTH Education is the newest of the professional specialties to be developed as a basic and essential element in the public health program. In the 19th century, the sanitarian and the bacteriologist were the dominant figures in the field. In the early 20th century, the physician and the nurse came into the picture. Today, our Committee on Professional Education has prepared detailed statements of educational qualifications for thirteen different types of specialists—with more to come. In none of the areas of service has development been more rapid than in that of health education. Ten years ago there were perhaps a dozen recognized experts of this kind in the United States. Today the accepted minimum standards for local health service list the health educator along with the administrator, the nurse, the sanitarian, the statistician, and the laboratory expert as a fundamental element in every program.

It seemed to the Editor desirable to see what all this shouting was about. We have, therefore, invited fourteen leaders in health education, approaching the subject from the differing viewpoints of the health officer, the physician, the nurse, the health council executive, the faculty member of the school of public health, the expert in school health, and the U. S. Public Health Service, to prepare brief and succinct answers to the question, "What Is Health Education?" The resulting symposium is presented—with much satisfaction—as the special review article in this issue of the *Journal*.

Frankly, we expected fireworks; and we are agreeably disappointed in this expectation, for the display is one characterized by much light and little heat.

Dr. Bauer and Miss Connolly emphasize the broad scope of the process of health education and the fact that it includes the impact of the whole of life's experiences, as affected by a wide variety of forces bearing on the health knowledge and practices of the individual. Dr. Dublin stresses the important rôle of the practising physician, whose direct contacts with the individual are central and determining in their influence; and Miss Fox elaborates the kind of personal guidance which is the prime factor in the activities of the public health nurse. Several contributors point out that among the forces which mould the health

consciousness of the public are many which are positively harmful in their trend, such as many forms of commercial advertising (Dr. Bauer), and the propaganda of cultists (Mr. Marquette). Dr. Derryberry notes that a hurried and inhuman clinic contact or a casual and superficial health examination may nullify all that has been accomplished by arduous efforts to cultivate a sense of the preventive service which the physician can and should render to the public.

The theme most commonly stressed by our contributors is that the object of health education is to mould conduct and that it is valueless unless it actually changes the habits of the individual. This is emphasized by Dr. Bauer, Dr. Derryberry, Mr. Green, Miss Jean, and Dr. Peter. Miss Fox and Mr. Green remind us that if success is to be attained, the program must be carefully planned so as to be purposefully directed at a given group, for the attainment of specific results. Mr. Groom underlines the importance of brevity and compactness and simplicity in producing maximum results with minimum effort. Dr. Bundesen cites the admirably efficient way in which the resources of a great city health department may be focused on the attainment of specific ends, such as immunization or infant care.

Health education, however, is something more far-reaching and more deep-seated than the important task of securing compliance with particular procedures. That is—after all—training, not education in the true sense of the term. Dr. Morgan points out that we must cultivate a general habit of mind as well as inculcate specific practices; and that in the field of public health this habit of mind must be grounded in a broad and fundamental social philosophy.

Finally, Dr. Nyswander and Dr. Wilson strike what is perhaps the most fundamental note of all. They point out that the important thing is "learning" not "teaching," and that conduct is not controlled by intellectual processes alone but by motivation. Unless the learner really *wants* what he has learned to be good, he will not seek it. The essence of a change in behavior is motivation, and motivation comes only through experience. The experience may be "learning by doing" or it may be "learning by feeling." It may involve a physical act leading to habit formation or an emotional experience such as may result from hearing a speech or seeing a poster. What is essential is that the learner—through act or feeling—shall himself make a contribution to the process. Without such active participation on his part, the seed will fall on stony ground.

A NATIONAL NERVE CENTER FOR PUBLIC HEALTH LABORATORY SERVICE

A YEAR ago (July, 1946) the activities of the Office of Malaria Control, which proved of such inestimable value during the war, were crystallized in what it is hoped may be a permanent form, through the establishment of a Communicable Disease Center of the U. S. Public Health Service at Atlanta, Ga. As the name of the new organization indicates, its scope of interest will be broadened to include any or all communicable diseases, although major emphasis will at first continue to be in the field where insect vectors or animal reservoirs are of importance. The functions of the center will include research and evaluation, training of personnel, and emergency service to communities where special problems may arise.¹

One of the most important elements in the program is the creation of a Division of Laboratory Services, described by Seward E. Miller at the Cleveland meetings of the American Public Health Association last fall.²

This division will fulfil three major functions: In the first place, it will continue intensive research on such problems as the serology of rickettsial diseases, precipitin tests for the type of blood present in the stomachs of mosquitoes, and the study of neurotropic viruses (carried on at the laboratory established at Birmingham, Ala., for rabies research by the Rockefeller Foundation). It hopes to extend its researches to the evaluation of the performance of various public health laboratory techniques (along the lines already established by the U. S. Public Health Service in connection with the serology of syphilis). Such studies are to be carried on in close coöperation with appropriate committees of the American Public Health Association and of the Conference of State and Provincial Public Health Laboratory Directors. They will not be directed toward any official U. S. Public Health Service standards but are planned as aids to the laboratory workers of the country in formulating and standardizing their own procedures.

A second function of the division will be direct consultation service to individual laboratories which may call for assistance. This may involve emergency epidemic aid where necessary; but will ordinarily consist in response to requests for advice as to particular procedures or the temporary assignment of laboratory personnel for the purposes of solving technical and administrative problems or improving techniques and practices. It is hoped that ultimately such service may be extended into the fields of biochemistry and hematology as well as microscopy and cultural and serological techniques. The division will also be concerned with the vital problems of laboratory design and equipment, working in coöperation with the new U. S. Public Health Service Division of Hospital Services. Federal assistance will be available, under an Act of the last Congress for public health laboratories, as well as for health centers and hospitals. The Committee on Laboratory Quarters and Equipment of the Conference of State and Provincial Public Health Laboratory Directors has been asked for aid in establishing minimum standards for such laboratories. When these standards are established, a number of designs and plans for such laboratories will be prepared.

A third important function of the Atlanta Center will be training of personnel. Progress along this line has already been instigated by establishing in Atlanta parasitology laboratories composed of equal units of helminthology, protozoölogy, and medical entomology. The staff of these laboratories is busily engaged in fulfilling the request of the American Society of Tropical Medicine that the U. S. Public Health Service give short refresher training courses in the laboratory diagnosis of tropical diseases. To date, five such 6 week refresher courses in the laboratory diagnosis of parasitic diseases have been taught, with particular emphasis upon malaria, amebiasis, leishmaniasis, schistosomiasis, echinococcosis, filariasis, and hookworm disease. The courses are given free of charge to qualified public health laboratory workers and now, by arrangement with the Veterans' Administration, about 12 or 13 students in each of our succeeding classes will be from the technical workers in the laboratories of the various Veterans' Hospitals' throughout the country. The educational program has been broadened by mailing out special teaching materials to some 173 laboratories which have expressed an interest in the project. This service was initiated with malarial smears but is being extended to include other parasitic materials and those relating to various types of communicable diseases. The participating laboratories will retain these slides and specimens, and thus will ultimately accumulate a considerable collection of demon-

stration and teaching material for reference study and for the training of new employees.

The experiences of the war have broadened our vision to recognize that "tropical diseases" or "exotic diseases" are diseases which occur most extensively in other countries but which may also, not infrequently, be present in our own land. The mechanisms developed to cope with temporary problems of the war emergency have been continued and expanded at the Atlanta Communicable Disease Center to provide a most valuable element in our permanent health defenses.

AN INGENIOUS YARDSTICK FOR MEASURING HEALTH STATUS

THE Editor has recently come across a new device for stimulating a local sense of unfilled needs in public health which produces somewhat striking results. How sound it is, must be left for the expert statisticians to decide.

This procedure has been introduced by Professor S. C. Mayo of the Department of Sociology of the North Carolina Agricultural Experiment Station¹ and has been extensively used in the recent campaign for additional funds to support the health and hospital program of that state.

Professor Mayo's procedure is—in essence—a modified method of computing age-standardized death rates, with a more rigorous yardstick. His objective is to make comparison for each age period with the lowest death rate for that period recorded in the 1940 Census for white persons in the urban or rural area of any state. The figures actually used are as follows:

Age Period, Years	Area Used	Deaths per 1,000
Under 1	Rural Oregon	28.4
1-4	Urban Wisconsin	1.4
5-14	Rural Arizona	0.5
15-24	Urban Rhode Island	0.8
25-34	Urban Massachusetts	1.3
35-44	Rural Kansas	2.6
45-54	Rural Iowa	5.2
55-64	Rural Arizona	11.5
65-74	Rural Arizona	27.3
75 and over	Rural Arizona	72.8

Professor Mayo, using these figures, computes that, if the minimum rates tabulated above had obtained in North Carolina, that state would have had 16,642 deaths in 1940. It actually had 31,904 deaths.

The procedure used obviously ignores racial and economic and climatic differences on the assumption that these differences may conceivably be overcome (which is certainly true of those relating to economic status). If such limitations are frankly recognized, stimulation of local pride to overcome existing obstacles, as far as possible, ought to prove wholesome. A question also arises as to the validity of rates (such as those for Rural Oregon and Rural Arizona) which are

based on populations of between 3,010 and 55,100 persons. (The lowest actual number of deaths at any age period is at age 55-64 for Rural Arizona.)

The technique, however, seems to offer an intriguing challenge. We would welcome correspondence on it, and particularly suggestions by statisticians as to the minimum populations which might be safely used in such an estimate. It would seem worth while to test a formula of this type by application to various communities and areas.

Report of the Archivist, 1946

Laboratory Section

AT the meeting of the Association in 1944 report was made that since all available early archival material appeared to have been deposited, it was planned to examine some of the items in detail for their value as historical records or for reference. It seemed logical to begin with an examination of the collected programs. This is the forty-sixth official meeting of the Section. Since it is almost a quarter of a century since the last meeting in Cleveland (1922), the program for that year was selected. A comparison of the programs of 1922 and 1946 gives a remarkable picture of the advancing place of the laboratory in the practical and academic fields of medicine and public health.

In 1922 the membership of the Association was less than three thousand, while now it is over ten thousand. The membership of the Section in 1922 was approximately 500, having also trebled in the twenty-four years to its present fifteen hundred. The character and scope of the work of the Section have also developed significantly.

Dr. Hitchens was secretary of the Section in 1922 and chairman of the program committee. The Section had two sessions. The program lists nine papers, one committee report, and the address of the chairman, Dr. B. L. Arms, Director of the Bureau of Diagnostic Laboratories of the Florida State Board of Health. At the present meeting, the Laboratory Section is scheduled for more sessions and for the presentation of a greater number of papers than any other section of the Association—eight sessions of the Section alone and one joint session, with a total of fifty-

eight presentations and eight committee reports. Moreover, the Conference of State and Provincial Public Health Laboratory Directors met for two full days before the Association meetings, with three sessions each day. This situation is all the more interesting when the constitutional restriction on the newly formed Laboratory Section in 1900 is recalled. The authorization for the Section, which was organized in 1899, reads:

"Meetings shall be held on the first day of the meeting of the Association and at such other times as may be decided upon, but no meeting shall be held during the time occupied by the meetings of the Association."

The contribution of the laboratory is further shown by an examination of the programs of 1922 and 1946 against a handwritten report in the archives of 1908 from Dr. Herbert U. Williams of the University of Buffalo—"A report on standard methods for laboratory diagnosis of syphilis."

". . . The outlook for the practical employment of laboratory methods in Board of Health work seems not very encouraging for the immediate future. . . . Attention must be paid to staining with aniline dyes, to silver impregnations, and to serum diagnosis. . . "

In 1922, fourteen years later, Dr. Young and Dr. Kahn reported on the use of the serologic test for syphilis in a public health laboratory; and intervening progress since 1922 is suggested by the important series of papers in Cleveland's program dealing with the standardization of laboratory procedures in the field of public health.

The keynote of the address of the

chairman¹ in 1922 was "Service." Dr. Arms said:

"I have selected the motto 'Service' as indicating what I feel the Laboratory Section . . . and the individual worker . . . should stand for.

"The laboratory worker has a real place to fill . . . Public health administrators all over the world are depending more and more on laboratory work to guide them in their endeavors to limit the spread of disease and, what is far more important, to prevent the occurrence of infection.

" . . . It is a fact that the keynote of our profession may be summed up in a single word — 'Service.' "

Certainly this attitude of service was outstanding in the career of Dr. Mazýck P. Ravenel, charter member, whose death has occurred since the last meeting, and whose contributions and achievements have been widely noted. The deaths of Dr. Ravenel and of twenty other members of the Section are here recorded with regret.

You will recall that in 1943 Dr. Wadsworth canvassed members of the Section to secure a record of services and activities in relation to the war at that time. It seems important to complete that project as far as possible by attempting to secure a final record by another questionnaire to the members.

Since the establishment of the office of archivist in 1935, the status and needs of the collection have been reported regularly. By action of the Council, the minutes of the meetings of the Section and of the Council are now deposited. No record of current activities of individuals, groups, or committees has been received, however, since 1941. As has been said in other years, the test of the archival quality of a record is still often taken to be that of age, but any document or correspondence that forms a part of an official transaction and that should be preserved for future reference should be deposited in the archives as soon as it ceases to be of current use. I therefore close with

a renewed appeal for an awareness of the value of each transaction related to the Section.

ANNA M. SEXTON

Public Health Interest in Pennsylvania

The Pennsylvania State Medical Society at its meeting in October, 1946, passed a resolution setting up a Commission on Public Health and Preventive Medicine within the society. Its chairman, Pascal Lucchesi, M.D., reported on the plans of this Commission at a recent annual meeting of the Pennsylvania Tuberculosis Society in Harrisburg.

He declared that the appointment of the Commission "marks the first official recognition of organized medicine in this state of the need for more active participation of this great medical body in the field of public health and preventive medicine."

Summarizing the difficulties created

in the state by its complicated public health laws and its more than 2,500 local health jurisdictions, he outlined the following goals of his Commission:

1. Stimulate the interest of the medical profession of the state in public health through the County Medical Societies.
2. Stimulate the establishment of a graduate school of public health and preventive medicine in the state.
3. Bring about the united action of doctors, dentists, nurses, and allied groups for a better program of public health in the state.
4. Bring about a complete public health survey of the state.
5. Prepare a model public health code.
6. Bring about the establishment of decentralized full-time local health units.
7. Study specific local public health problems.

Coördinating Committee on Standard Methods

Laboratory Section

Personnel Changes—A. Parker Hitchens, M.D., Robert S. Breed, Ph.D., William D. Stovall, M.D., and Friend Lee Mickle, Sc.D., resigned as chairmen of their respective committees functioning under the Coördinating Committee on Standard Methods, and the resignations were accepted. Col. Hitchens, who had been chairman since the committee was originated, was commended on the accomplishments of the committee and was made an honorary member of the committee. A. H. Robertson, Ph.D., was elected Chairman of the Committee on Examination of Dairy Products, and Ralph S. Muckenfuss, M.D., Chairman of the Committee on Diagnostic Procedures and Reagents. The Committee for Frozen Desserts and Ingredients was put in Dr. Robertson's hands, at least until a permanent chairman is elected. Edmund K. Kline, Dr.P.H., as ex-officio secretary of the committee, was replaced by Geoffrey Edsall, M.D., the incoming Section secretary.

Committee on Examination of Water and Sewage—Walter L. Mallmann, Ph.D., is active in work preparatory to the publication two or three years hence of a 10th edition of *Standard Methods for the Examination of Water and Sewage*. John F. Norton, Ph.D., chairman of the Editorial Committee for the 9th edition of the water and sewage report, gave assurance that the 9th edition will soon appear, with a 1946 date.

Committee on Examination of Milk and Dairy Products—Dr. Breed presented a manuscript for the 9th edition

of *Standard Methods for the Examination of Dairy Products* that was accepted by the Laboratory and the Food and Nutrition Sections, the councils of those Sections, the Coördinating Committee on Standard Methods, and the Association for publication. Dr. Robertson, who had been chiefly responsible for editing this edition, was elected chairman of the committee replacing Dr. Breed. Dr. Breed was continued as chairman of the Editorial Committee for the 9th edition of the dairy products report. *Committee for Frozen Desserts and Ingredients*—The report of this committee revealed that several new procedures for examining frozen desserts and ingredients will appear in the 9th edition of the milk and dairy products report and procedures for sediment will be deleted as impracticable. The manuscript has been edited by Dr. Robertson and is ready for publication with the report from Dr. Breed's committee.

Committee on Diagnostic Procedures and Reagents—Dr. Stovall had submitted his resignation some time previously and the resignation was accepted at this meeting when it had been ascertained that he would no longer continue as chairman. Dr. Muckenfuss has accepted the chairmanship. It will doubtless be necessary for him to form an essentially new committee to begin preparation for the 3rd edition of *Diagnostic Procedures and Reagents*.

Committee on Virus and Rickettsial Diseases—Thomas Francis, Jr., M.D., and his committee presented an outstanding panel discussion before the

Laboratory Section at Cleveland. It was realized by those who heard it that the techniques for virus and rickettsial diseases are in much more complete form for publication than most of us had realized. At a very enthusiastic meeting of the committee a deadline of March 1 was set when the manuscripts are to be in the hands of Dr. Francis preparatory to a recommendation from that committee that a volume of laboratory techniques for virus and rickettsial diseases be published by the Association as promptly as possible.

Committee on Biological Products—In the absence of Dr. Robinson, the chairman, no meeting of the committee was held and no report submitted.

Committee for the Examination of Germicides and Antibacterial Agents—Your chairman does not know whether or not a meeting of this committee was held at Cleveland. Several interesting papers were presented by referees working under Stuart Mudd, M.D., in connection with the activities of this committee and some of them will certainly merit publication. Your chairman does not know whether publication in the *Journal* will take care of the accomplishments of this committee or whether a volume similar to that published by other committees is planned.

Committee on the Biology of the Laboratory Animal—In the absence of R. A. Kelser, Ph.D., the chairman, no report of this committee was rendered and no meeting was held.

Committee on Examination of Shellfish—James Gibbard reported activity on the part of this committee with considerably revised methods about ready for publication.

Possible Committee on Stains and Staining Technique—It is understood that E. K. Kline, Dr.P.H., was elected the Laboratory Section representative on the Commission of Biological Stains. Your chairman was informed that the

work of that commission is expanding and that the commission would be glad to have the activities affecting public health laboratory work taken over pretty much by a committee of the Laboratory Section that might very well function under the Coördinating Committee on Standard Methods. The proposal was made that Dr. Kline might be invited to attend the next meeting of this committee to outline the activities contemplated.

SUMMARY

It can be seen even from this brief resume that the CCSM is one of the active, productive committees of the Association. We all realize the rapidly changing character of public health laboratory work in most of its ramifications at the present time. The efforts of the committees functioning under CCSM bid fair to produce far-reaching results. Apparently it is the function of the CCSM to stimulate these activities and coördinate them in every way possible. Your chairman feels most humble regarding his ability to be of service in this capacity. He can help arrange for meetings of this group so that the activities will be coördinated, and he can transmit the accomplishments to the Section and to the Association through the Committee on Research and Standards for action.

At the Cleveland meeting there was some expression of feeling that in its expanding functions the Coördinating Committee may have outgrown the Laboratory Section and that it may need to be raised to an Association level. A subcommittee of the Committee on Research and Standards has been appointed to consider the status of CCSM as a committee. Suggestions from each member to the chairman of the committee is desired toward a solution as to how the best future accomplishments can be secured.

PROPOSED MEETING

There seems to exist a real need for a meeting of CCSM in the rather near future. Some day during the second week of January in New York City has been proposed. This brief resume of

the committee activities may serve as a sort of springboard to the development of agenda for the meeting. Comment and suggestions are requested.

FRIEND LEE MICKLE, Sc.D.,
Chairman

Proposed Federal Program for Circulatory Diseases

On February 26 Senator Claude Pepper of Florida introduced a Bill (S. 720) which has been referred to the Committee on Labor and Public Welfare, authorizing and requesting the President to undertake to mobilize at some convenient place or places in the United States an adequate number of the world's outstanding experts and to coördinate and utilize their services "in a supreme endeavor to discover new means of treating, curing, and preventing diseases of the heart and arteries."

The Bill briefly authorizes the President to undertake "in whatever manner he may deem most appropriate" to

bring together outstanding experts from any country and to coördinate their services "through the Surgeon General of the U.S.P.H.S., or through an independent group appointed by him." The President is also authorized to build needed clinical laboratory research facilities in order adequately to approach this problem, which, according to the Bill, involves the death of more than 587,000 persons a year in the United States and which causes disability to more than 7 million persons.

The Bill authorizes the sum of \$100,000,000 to be appropriated for these purposes.

Standard Methods for Dairy Products

Laboratory Section

THE Committee on Standard Methods for the Examination of Dairy Products wishes to present a 325 page manuscript covering the proposed ninth edition of *Standard Methods for the Examination of Dairy Products* of the American Public Health Association. This report is the work of four groups: (1) Committee on Milk and Milk Products of the Laboratory Section, (2) Committee on Frozen Desserts and Their Ingredients of the Laboratory, and Food and Nutrition Sections, (3) Committee on Assay of Foods of the Food and Nutrition Section, and (4) the Association of Official Agricultural Chemists.

Directions for some of the older technics have been improved and a few new and promising technics have been introduced. Among the new methods are the resazurin test, the methods that have been developed by the Federal Food and Drug Administration for determining the amount and type of extraneous matter in dairy products other than market milk and cream, and methods for the bacteriological examination of stabilizers used in frozen desserts.

Only two changes in commonly used technics will cause enough change in results secured to be worth mentioning:

(a) The temperatures given for the incubation of agar plates in the eighth edition are 32° or 37° C. After consultation with the Directors of State and Provincial Laboratories and others,

the incubation temperatures have now been established at 32° C., or at 35° C. This will increase the accuracy of results especially where the temperature used is 32° C. However, those laboratories that lower the temperatures used for agar plates will secure somewhat higher counts than they have had previously. Administrators should therefore modify enforcement procedures until the industry has been able to adjust itself to the more severe requirements.

(b) The hourly inversion of tubes during incubation of samples for the methylene blue reduction test will cause reduction to take place somewhat more quickly in certain samples of milk, and there will be a greater accuracy in the results secured.

The committee is deeply concerned over the findings reported by Black (*Public Health Reports*, U.S.P.H.S., 58:1605, 1641, and 1681, 1943) which showed that many laboratories do not follow essential requirements outlined in *Standard Methods* for making bacteriological analyses of dairy products. These findings should not be ignored. The records indicate that laboratory work is best done in those areas where state or provincial departments of health supervise the methods used in milk control laboratories in their respective jurisdictions.

Supply houses report that thousands of bacteriological incubators of the type that are heated with high temperature hot plates in the bottom of the chamber have been sold during the past year. From this it may be presumed that little heed is paid to the warning in the *Standard Methods Report* since 1939

* Report of the Joint Editorial Committee for Standard Methods for the Examination of Dairy Products.

that incubators of this type are unsatisfactory for milk work.

Some additions have been made to the Chapter on the Determination of Vitamins by the committee of the Food and Nutrition Section. These consist of methods for the determination of vitamin B, B₂ and niacin.

The most important improvement in the new report has been made by Dr. A. H. Robertson. He has edited the entire text so as to give the reports of the various referees a uniform simple and direct style. A simple cross-reference system has also been introduced. Discussions of the applications and limitations of the various technics have been rewritten by Dr. Luther Black, and have been segregated in a separate chapter at the beginning of the report.

All of this editing and rearrangement will lead to better indexing that will make the report more usable, thereby fully justifying the printing of a new edition.

R. S. BREED, PH.D., *Chairman*
A. PARKER HITCHENS, M.D.
F. LEE MICKLE, Sc.D.
H. T. SCOTT, PH.D.
A. C. HUNTER, PH.D.*

* Deceased.

Action was taken at the Cleveland meeting by all of the Section groups and by the Association Committee on Research and Standards recommending to the Governing Council the publication of this manuscript as the Ninth Edition of *Standard Methods for the Examination of Dairy Products*.

Examination of Frozen Desserts and Ingredients*

Laboratory and Food and Nutrition Sections

IN the last report of this committee it was stated that a manuscript revision of the text of the 8th edition of *Standard Methods for the Examination of Dairy Products* had been prepared by Dr. A. H. Robertson preliminary to the preparation of the 9th edition of that report, the purpose being to have a revision of the entire text prepared by one individual with the elimination of inconsistencies in directions written by different referees. At the time that the last report was written the activities of the referees in the preparation of methods had been nearly completed and all that remained for the Committee to do in preparation for the 9th edition of *Standard Methods for the Examination of Dairy Products* was to work with the Standard Methods Committee on Milk and Milk Products of the Laboratory Section and with Dr. Robertson as editor of the 9th edition to complete the revision of the text to conform with the text for the other portions of the publication.

Two meetings of the Standard Methods Joint Committee on Frozen Desserts and Ingredients have been held since the last report was submitted. Both were held jointly with the Committee on Milk and Milk Products of the Laboratory Section. The meetings were well attended and real progress was made toward publication of the

forthcoming edition of the dairy products report.

In the preparation of the 9th edition much effort has been expended in getting the technical procedures into an imperative form which it will be easy for laboratory workers to follow. In doing this it was found desirable to sort out the material dealing with the interpretation of results and the discussion of the uses and limitations of methods and remove it to a separate chapter where it has been combined with similar material regarding milk and other milk products. It is believed that in this form the new new edition of *Standard Methods* will be much more serviceable not only to laboratory workers but also to control officials.

The accomplishments of the committee in preparation for the 9th edition of the dairy products report can be summarized as follows:

1. Methods for the microbiological examination of stabilizers have been included among the technical procedures.
2. Directions for determining the weight per unit volume of ice cream have been incorporated as determined by the Gibbard and by the Hart Method.
3. The sediment test methods for frozen desserts and for frozen dessert ingredients that appeared in the 8th edition have been deleted as they were deemed impracticable.
4. A suggestion has been made in the 9th edition that one or more modifications of the methods for extraneous matter in dairy

* Report of the Joint Standard Methods Committee.
STANDARD METHODS COMMITTEE ON FROZEN DESSERTS AND INGREDIENTS
Organized 1937. Published reports: *Year Books* 1937-1938, 1939-1940, 1940-1941, 1941-1942,
A.J.P.H., May, 1943, Aug., 1945.

products may be adapted to the detection and determination of filth and foreign matter in both frozen desserts and frozen dessert ingredients

5. Applications, with precautions, of the phosphatase test are suggested for use on finished frozen desserts

There has been considerable discussion among the members of the committee of proposals relative to (a) weighing out the first portion of frozen desserts while the material is still frozen, and (b) reconsideration of the procedures for coliform determinations in frozen dessert products. These rather controversial matters probably will require further study before directions can be prepared that will be acceptable to all who are interested in these procedures.

Dr. K. G. Weckel, University of Wis-

consin, Madison, Wis., was appointed referee for sediment test methods in frozen desserts to fill the vacancy mentioned in the last committee report.

It is suggested that the Laboratory Committee of the Joint Committee on Frozen Desserts and Ingredients might well be discontinued with the publication of the 9th edition of *Standard Methods for the Examination of Dairy Products* as the present activities of the committee will be completed when that work is published. Any studies on frozen desserts to be undertaken in preparation for a 10th edition of *Standard Methods* might well be taken under consideration by the Committee on Milk and Milk Products.

Examination of Water and Sewage*

Laboratory Section

YOUR committee is glad to report that the ninth edition of *Standard Methods for the Examination of Water and Sewage* is now in press. The ninth edition has been delayed in preparation largely because of many obstacles caused by the war.

The work of your committee has been completed with the publication of the ninth edition. It is suggested that a new committee be appointed immediately to plan for the tenth edition, as there are already many suggestions which have been received on improvements of methods which will appear in the ninth edition.

Dr. George E. Symons, who has been employed to edit the ninth edition by the Joint Editorial Committee makes the following recommendations in regard to future editions:

A Joint Editorial Board for the tenth edition should be formed and begin work as soon as the ninth edition is off the press.

The tenth edition should be published not later than early 1950, as many of the methods in the ninth edition are already subject to criticism. Publication in 1950 means that revision of the text must be accomplished by the spring of 1949 in order to allow one year for final editing and printing.

Each association interested in *Standard Methods* should have a committee devoting its energies to that subject with the membership being chosen with full consideration of geographical location, laboratory facilities, and laboratory interest of the members.

These committees may find it helpful to adopt the system used by the *Standard Method*

Committee of the Federation of Sewage Works Associations, namely that all of the material falling within their provinces of interest be circulated throughout the entire committee membership for comment, correction, addition, editing, etc.

Chemical methods, etc., should be reviewed by members of the American Chemical Society as well as by committee members of the *Standard Methods Committees* of the A.P.H.A. and A.W.W.A. Methods dealing with microscopic analysis and bacteriological analysis should be referred to the pertinent cooperating committees, and sewage tests should be referred to the Federation of Sewage Works Associations Committee.

It has been suggested that the Joint Editorial Board, when appointed, should review on the broadest possible basis, the functions for which it was established and report to the governing bodies of constituent associations its decision as to the proper activities it will undertake.

Heretofore the Editorial Board has concerned itself only with appraising published methods. It has been suggested that the Joint Editorial Board extend its activities to the field of developing new and better methods of analysis.

Objections have been raised to this suggestion for broadening the scope of the Joint Editorial Board. A compromise between these two viewpoints appears desirable. Perhaps the Joint Editorial Board should broaden its scope to the extent that it assemble opinions as to the weaknesses of individual

* Report of the Standard Methods Committee.

Organized 1899. Reorganized 1933. Published reports: *Year Books* 1930-1931, 1934-1935, 1935-1936, 1937-1938, 1939-1940, 1941-1942, A.J.P.H., May, 1943, Aug, 1944, Sept., 1945. 9 volumes published: 1905, 1912, 1917, 1920, 1923, 1925, 1933, 1936, 1946.

Clearing House on Public Health Salary Information

WITH the introduction of this informal and temporary department of the *Journal* in the May issue (page 576), the Editors promised to collect information about salaries of public health workers from the sources available to them, and invited readers to participate in the discussion.

We present herewith the month's gleanings. The items are in no special

order other than that given them by the make-up man. If they prove anything it is that a ferment is at work and various groups in public health are beginning to raise their voices in their own behalf for recognition of the monetary value of their services.

Next month we hope to publish a recommended salary scale for health officers approved by the Executive Board.

THE CANADIAN SALARY STUDY

The Canadian Public Health Association has recently published the findings of its Committee on Salaries and Qualifications of Public Health Personnel.¹ This committee declares at the outset, "If it is agreed that 'public health is only as successful as the people in it,' then the logical answer to procurement of 'successful people' is first to train them properly and then to make the public health positions in official agencies attractive enough to hold them. It should be obvious that it is economically unsound to spend money training personnel for public health and then lose them, for financial reasons, to other agencies or to private endeavor."

Acting on this faith, the Canadian committee makes salary recommendations in several grades for each of the professional groups working in public health in the dominion—physicians, nurses, engineers, laboratory and statistical personnel, nutritionists, veterinarians, and sanitary inspectors. The

recommendations indicate an awareness of the fact that the prevailing salary levels must be raised if "public health positions in official agencies" are to be made "attractive enough" to hold trained workers.

Because of the differences in cost of living, the actual recommended rates for personnel in Canadian official agencies have limited usefulness for the United States. What is important, however, is the bold, sure recognition that the most important single action needed currently to secure and retain adequately qualified personnel is to raise salaries. Within a year after the Canadian Public Health Association was requested by the Dominion Council of Health to make a salary study and recommendations, the report was completed and published for distribution. Whatever may be its limitations, it at least has done the first most important job; it has started the thinking and planning for better public health salaries.

¹ Report of the Committee on Salaries and Qualifications of Public Health Personnel. Canadian Public Health Association. *Canad Pub Health J.*, 38:1, 1-37 (Jan.), 1947.

ENGINEERING SECTION COUNCIL ON SALARIES

At its meeting on February 10, 1947, the A.P.H.A. Engineering Section Coun-

TABLE 1

Federal Civil Service		Engineering Society	
Grade	Salary Rates	Grade	Salary Rates
P-1	\$2,645-\$3,400	I	\$2,700-\$3,400
P-2	3,400- 4,150	II	3,400- 4,200
P-3	4,150- 4,902	III	4,200- 5,100
P-4	4,902- 5,905	IV	5,100- 6,100
P-5	5,905- 7,102	V	6,100- 7,250
P-6	7,102- 8,180	VI	7,250- 8,600
P-7	8,180- 9,975	VII	8,600-10,350
P-8	9,975-10,000	VIII	10,350-12,600
P-9	10,000 and up	IX	12,600 and up

cil adopted the following statement of principle:

In view of the existing demand for engineers, it appears impossible to recruit and retain qualified public health engineers unless salary scales are comparable to those obtainable in other fields of professional engineering, as exemplified by the salary schedule prescribed by the American Society of Civil Engineers and those in effect under the Federal Civil Service, as shown in the attached table.

The salary schedules referred to in this statement of principle each provide for nine grades of duties and responsibilities and thus of salaries. The first grades are listed at \$2,645-\$3,400 and \$2,700-\$3,400 respectively for Federal Civil Service salaries and for salaries recommended by the American Society of Civil Engineers. Grade 9 figures are \$10,000 and up and \$12,600 and up respectively. In the intervals between, the Engineering Society's recommended starting salaries are progressively higher in each grade than those paid currently by the federal services.

The scales for the Federal Civil Service and the recommended salaries of the Engineering Society are shown in Table 1.

RECOMMENDED SALARIES—PUBLIC HEALTH NURSES

A newly graduated public health nurse without experience or special advanced preparation receives between \$2,200 and \$3,300 in voluntary health agencies, and in state or local official

agencies; the same nurse in the employ of the federal government receives between \$2,644 and \$3,397, one-fifth more at the lower level and 3 per cent more at the upper level. This is the information shown in the most recent salary data published by the Nursing Information Bureau¹ in March, 1947.

For "positions attained on the basis of successful experience in nursing and/or supplemented by advanced or special preparation," the lowest salaries reported are the same as for the newly graduated nurse. The maximum salary in state or local official and voluntary agencies is \$9,500; in the federal service it is \$8,059, or about one-sixth less. These ranges apply to a wide variety of positions—from staff nurse rendering general service to director or educational director, consultant, or professor of public health nursing.

More recently the National Organization for Public Health Nursing has published its recommendations for current public health nursing positions.² Two salary levels are suggested for staff nurses; from \$2,400 to \$2,640 for the graduate registered nurse who has not yet completed an approved program of study in public health nursing, and might thus be thought of as an apprentice in public health, and \$2,520-\$3,300

1. Of the American Nurses Association, cooperating with the National League of Nursing Education and the National Organization for Public Health Nursing.
2. *Pub. Health Nurs.*, 32, 5:237-239 (May), 1947.

for the graduate registered nurse who has completed an approved program of study in public health nursing. The latter beginning salary is 5 per cent below that for federally employed public health nurses who begin at \$2,644 and must also have completed an approved program of study in public health nursing.

The National Organization for Public Health Nursing does not make salary recommendations for positions such as administrators, supervisors, consultants, instructors and others, saying only that "they would of course be proportionately higher depending upon the extent of responsibility and qualifications required."

SUGGESTED SALARIES FOR PUBLIC HEALTH LABORATORY PERSONNEL

At a recent joint meeting of the Association's Laboratory Section Council and the Laboratory Section Coordinating Committee an agreement was reached as to basic minimum recommended salaries for professional laboratory personnel. The salaries recommended are based upon the qualifications as outlined in the Report on Educational and Experience Qualifications of Public Health Laboratory Workers as recommended by the A.P.H.A. Committee on Professional Education and approved by the Governing Council in 1943.¹

They are as follows:

Laboratory director	\$7,500 and up
Assistant director	6,000-\$7,000
Principal bacteriologist	4,000- 5,000
Associate bacteriologist	3,600- 4,500
Senior assistant bacteriologist..	2,800- 3,500
Junior assistant bacteriologist..	2,400- 3,000

FOOD FOR THOUGHT

Minnesota's Health for March (Vol. 1, No. 3) in "Where Are They Now?" reports that, of 242 persons trained by

the Minnesota Health Department since 1932, only 91 are still doing health work in Minnesota. It uses pictographs to show how extensively the various professional groups have strayed from their own training area. Engineers have the best record, 20 of 38 trained still in public health activities in the state. Unfortunately the retired, died, or status unknown groups are all classified together and make up one-third of the nurses. Of the remaining nurses trained, more than half are still in service in the state. The Minnesota bulletin does not philosophize about the reasons for the loss of nearly half of the still active workers whom it trained. However, since more than one-fourth of those known to be working are in public health work outside of the state and one-fifth have gone into private practice or industrial service, the connection between this turnover and salaries seems obvious.

SALARY STUDY UNDER WAY BY STATE AND PROVINCIAL PUBLIC HEALTH LABORATORY DIRECTORS

The Conference of State and Provincial Public Health Laboratory Directors has an active Committee on Qualifications and Salaries of Laboratory Personnel. Its Chairman is Miss Myrtle Greenfield, Director of the New Mexico State Health Department Laboratory, Albuquerque. This committee is studying current salaries and vacancies in state health department laboratory divisions with a view to arriving at salary recommendations. It has sent out questionnaires to all state health departments. As soon as these have been returned they will be analyzed and used as the basis for salary recommendations for laboratory personnel in official agencies throughout the country.

WHAT THE READERS SAY

Dr. Henry F. Vaughan, Dean of the School of Public Health, University of

1. *A.J.P.H.*, 33, 7:882-887 (July), 1943.

Michigan, Ann Arbor, Mich., writes:

"I have a very strong conviction that salaries constitute the greatest single barrier to securing an ample supply of well trained and experienced career people in public health administration. If I were to list the ten most important causes for our inability to personnel our health departments, I would put salary in first, second, and third place.

"We must impress upon the public mind the fact that the director of a public health department is a trained health specialist whose salary should be commensurate with the income of other specialists in the medical field. The highest compensation in county or city government should go to the director of public health and the superintendent of education who have devoted years to their professional training and who because of their responsibilities and professional background are not to be compared with elective public office holders who usually have a business, trade or pro-

fession other than that of government.

"A real contribution can be made by the public in focusing attention upon the essentialness of making public health practice a professional service with adequate compensation and encouragement to those who prepare for and serve in this field. Business men, industrialists, and lay organizations can see to it that suitable remuneration for the public health officer is forthcoming, even though in some instances it is necessary to augment the public appropriation with temporary financial support from lay sources. This latter is suggested as a temporary expedient during the days of extreme shortage of personnel and a stop-gap until there can be a more general recognition of the need for adequate compensation. After all, the whole question resolves itself into one of competition. There are too many public health men resigning their positions to accept the more lucrative opportunities of private practice."

Credit Lines

CONTROLLING HAY FEVER IN NEW YORK

Recently completed at New York University (New York City) was a course of instruction in Methods of Control of Plants Detrimental to Public Health. Planned by an advisory committee of representatives of the health departments of New York City and Westchester County, New York, and the two metropolitan counties in New Jersey, Bergen and Hudson, it was designed to instruct health officers and others in carrying out a program of weed control in the metropolitan area during the summer of 1947.

The course was attended by more than 100 persons. In addition to the nearby communities represented there were students from Albany, Philadelphia, Connecticut, New Hampshire, and Cincinnati. The series of six lectures was priced at \$5, with registrations accepted only for the entire series.

Partly as a result of this series, the Brooklyn Botanic Garden (N. Y.) in April sponsored a meeting of the metropolitan area garden clubs and health departments to consider the problem of weeds detrimental to public health. Included in the 1947 programs of the garden clubs will be the detection and elimination of ragweed and other weeds injurious to health.

FACTS ABOUT THE WORLD HEALTH ORGANIZATION

If you have missed any of the significant details about the World Health Organization in newspapers or other journals, a recent publication of the Interim Commission will fill in the gaps. A *Fact Book* of 15 mimeographed pages summarizes the background and origin of the WHO, what its current functions are, with particular reference

to those taken over from UNRRA, the League of Nations, and the Office International d'Hygiene Publique. A list of publications, a bibliography, and general information as to headquarters and officers are included.

The Interim Commission's Headquarters office is at 6306 Empire State Building, New York. Brock Chisholm, M.D., is Executive Secretary, and Frank A. Calderone, M.D., is Director of the headquarters office. The Deputy Executive Secretary of the Interim Commission, Dr. Yves Bifaud, is in charge of the technical office in the League of Nation Building, Geneva.

The *Fact Book* is available from the Headquarters Office, World Health Organization, 350 Fifth Ave., New York 1.

TRIBUTE TO CLIFFORD CAUDY YOUNG

Many readers of the *Journal* will remember "Cy" Young, handsome, debonair, courageous in the face of an incurable cancer through which he lived ten years instead of the two that he was given by his doctors. Now Paul de Kruif has brought him to life for us again in "Anonymous Doctor to Five Million" in the April *Reader's Digest* (Pleasantville, N. Y.) In swift and moving style is told how he built the Michigan State Laboratories. His drastic reduction of the state's diphtheria death rate, his work in discovering the cause of Michigan's widespread goiter and the means of preventing it, putting the laboratories at the disposal of private physicians, the development of the Kahn test, the growth of Dr. Kendrick's pertussis vaccine experiments, the building of a virus laboratory, the provision of free pneumonia serum and free blood plasma—all these are re-

ported with the background of ingenuity, righteous indignation, and utter selflessness with which Young got funds from reluctant legislators. For example, when legislators objected to the cost of free blood plasma, he growled, "You can bury a baby for \$125. It might cost all of \$500 to save that kid with commercial plasma. If you want to bring money into this argument, its cheaper to let the babies die!"

C. C. Young died on June 5, 1944, before he had time to carry out his program, already mapped out, for providing free penicillin to all who needed it and could not otherwise afford it. In a real sense he lives in the C. C. Young Public Health Laboratory at Lansing in the 22 buildings of which his work and his spirit are radiating to all of Michigan and indeed to much of the world.

HEALTH OF FARM WORKERS

The January *Health Bulletin* of the North Carolina State Board of Health reports a project that could well be repeated in other areas. Late in 1947, the manager of the 22,000 acre Braswell Farms, located in Nash and Edgecombe Counties, arranged for a mass health survey of the farm employees. By arrangement with the health officers of the two counties the 900 persons in the 140 families employed by the farm were brought to the county health center where they received complete physical examinations, including chest x-rays provided through the State Department of Health's Mobile X-ray Unit. Blood samples were sent to the State Laboratory for analysis. The examination included dental inspection and a check up on vaccinations of children under six. It will be interesting to watch this project and the degree to which it succeeds in its aim of remedying as far as possible any defects.

One immediate by-product of the project, chest x-rays were offered to all inhabitants of the two counties.

INDUSTRIAL MASS X-RAYS

X-ray the Picture of Health is produced by the Health Education Division and published by the Tuberculosis Control Division of the New Jersey State Department of Health. It is a brief outline of the program of free chest x-rays for industrial employees. As background it gives briefly the tuberculosis mortality rates and the age incidence.

The illustrations are made up of letters or newspaper clippings about those plants in which workers have already been x-rayed. The list of nearly 100 plants is also included. Ring bound in a stiff red, white, and blue cover, it is an effective piece of specialized health education.

ART SERVES PLASTIC SURGERY

Artist Virginia A. McCall was recently announced as the winner of the 1946 Gimbel Philadelphia award of \$1,000 given annually to a woman who has done outstanding work for humanity. She was cited specifically for assisting surgeons in plastic operations by making drawings of the patients for use by the doctors. She has also worked with bed patients in Veterans' hospitals, teaching them to make wood cuts, drawings, and water colors.

LEARNING ABOUT HEALTH IN SCHOOLS

We have decided that there is literally no end to the variety of ways in which communities can be made public health conscious. Credit Lines has recently been sent three issues of *World Week*. In case you are a stranger to it, as we previously had been, this is a national weekly magazine and is intended for the use of teachers of social science studies in high schools.

The three articles that interested us are "Keep Yourtown Healthy" (Feb. 3), "Yourtown's Hospital" (Feb. 10), and "Take It Away!" (Feb. 24). The first is about the local health department, the six standard functions that it

should carry on and the necessity for organizing in units large enough to do effective work. The second outlines briefly the need for hospital service and how each community can organize to meet these needs. The third deals with garbage and sewage disposal.

Each of these is written in a breezy style that relates the problems to the child's own home town. Photographs and anecdotes are used for illustration. Further, it has both a teachers' and a student edition.

If you have not seen this magazine you will perhaps want to send for a sample copy. Address, *World Week*, 220 East 42nd Street, New York 17. Group rates 50¢ a semester or \$1.00 a year; teachers' edition \$1.50 a year.

NASHVILLE'S NEW HEALTH BULLETIN

With February, 1947, The Health Advisory Committee of the Nashville, Tenn., School Health Service issued Volume I, No. 1, of *Health Bulletin* intended for teachers. It is full of ideas for health education. In the first issue are discussions of tuberculosis with special reference to "X-ray Program for City Schools," "Better Breakfast Week," "Physical Examinations." List of films and film strip and a "Did You Know That" department. Mimeographed, and with very simple, almost crude line drawings, it is nevertheless extremely effective.

WIDE USE OF CANADIAN V.D. FILMS

Canada's Health and Welfare (Feb. 1947) justifiably points with pride to the international recognition given its V.D. films. Very Dangerous, for male audiences, has been purchased by the Michigan and Hawaii boards of health and four commercial film libraries in the United States.

Sixteen to Twenty-Six, designed for women and girls, has been ordered by the U. S. War Department in sufficient quantity for all Women's Army Corps

training centers, all army area overseas libraries, and for the Signal Corps' library in Nanking. It is also being used in 13 "government girl" residences by the employees health service division of the U. S. Public Health Service. Over a dozen prints have been sold to the U. S. offices of the National Film Board.

Both films aroused considerable interest when they were shown at the annual meeting of the American Public Health Association in Cleveland last November. They are 16 mm. color films with commentary by the late Dr. J. J. Hagerly, former federal director of the Canadian Health Service. Available from the National Film Society of Canada, 172 Wellington Street, Ottawa.

IS DIABETES COMING UNDER CONTROL?

The Prudential Insurance Company of America (Newark, N. J.) has announced that under certain conditions, it will now insure men and women who are under treatment for diabetes. The announcement credits this move to the advances made in the treatment of diabetes in the past 25 years. It is careful to say that not all sufferers from this disease will be accepted but only those whose medical history is favorable.

N F I P IN 1946

The eighth *Annual Report*, (year ending May 31, 1946) of the National Foundation for Infantile Paralysis follows upon the most severe epidemic of polio since 1916. It tells how the serious epidemics were handled first in Utah, then Illinois. Other states with serious outbreaks were New Jersey, Tennessee, Texas, Wisconsin, Montana, Iowa, and Washington. The emergency care, together with the long-time programs, have been a heavy drain upon the funds of the Foundation.

Among the new developments described are the PEV's, Polio Emergency Volunteers, which are units of specially

trained women in bedside care of polio patients. They do non-paying non-professional tasks, thus leaving hospital staffs freer for the skilled tasks. During the year there were 2,000 such volunteers in 75 communities of 31 states. The Foundation now has 54 state offices and local chapters in 2,712 of the 3,070 counties.

Another development was the epidemic aid unit, made up of an orthopedic surgeon, orthopedic nurse, and two physical therapists. Each unit is "on call" by epidemic areas, to organize and supervise treatment until the community can recruit personnel to meet its needs. Such units have been established in coöperation with Harvard, Northwestern, and Stanford Universities, and the Watson School of Physical Therapy in Pennsylvania.

The report gives a complete report of the grants and appropriations authorized by the Foundation during the year, indicating in each case both purpose and agencies to which grant was made. In summary they are:

For virus research.....	\$1,259,153
For research for the prevention and treatment of after-effects.....	599,674
For medical care.....	2,612,303
For education.....	3,102,585
Total.....	\$7,573,715

Total disbursements against these grants and those authorized in prior years were \$4,632,289.

HEBREW MEDICAL JOURNAL

Harofe Hivri (The Hebrew Medical Journal) 983 Park Ave., New York 28, which is dedicated to the continued growth of Hebrew medical literature, has concluded its 19th year of publication. Published semiannually, this journal is bilingual, one-half of each volume being printed in English, the other half in Hebrew. The journal has thus been of particular service to the medical department of the Hebrew University in Jerusalem.

Among the articles published in the English language in the 1946 volumes, public health workers would be interested in a report on "The National Workers' Sick Fund" and a description of "Hygiene and Sanitation among the Bedouins in Palestine." There are also two historical articles, one on the 10th Century Sabbathai Donnolo and the other on the ethics of Jewish physicians in ancient Hebrew Literature.

MINNESOTA ACTIVITY

We recently welcomed *Minnesota's Health* to the writing fraternity (March, p. 317). Now comes *Minneapolis Health News* also having started in January, 1947, with Vol. 1 No. 1. No doubt of it, the current air of Minnesota is energizing.

Minneapolis Health News is an attractive mimeographed four pages. Its first issue gives a brief history of early public health departments in states and cities. It also discusses the health bills currently under consideration by the Minnesota legislature, chiefly the Health Service Enabling Act. This would authorize county or multi-county health departments. It points out that the proposed act is the result of more than a year's work by a citizens' committee, the Minnesota Committee on Local Health Services.

TWO YEARS OF THE EYE BANK

About two years ago the Eye Bank for Sight Restoration in New York City was established. It has a threefold purpose: to take care of the supply and distribution of eyes the healthy corneal tissue of which is to be used in restoring sight to those blind or with defective sight because of injury or disease to the cornea, to train young surgeons in the technique of this transplantation operation, and to encourage research studies in the sources, preservation, and handling of the materials by laboratories or research workers.

With the coöperation of the American Red Cross and Eastern Air Lines, eyes are now often flown to the physicians who need them. This obviates the necessity of long and expensive travel for the patient whose sight is to be restored. The mere mechanism of listing needs, determining priorities, and getting doctor and patient notified as soon as an eyes becomes available is an invaluable service without which many of the operations to restore sight could not be performed.

The Eye Bank maintains a Laboratory for Ophthalmic Research whose director is Herbert M. Katzin, M.D. It has 50 affiliated hospitals in New York State and 27 in 8 other states. In mid-1946 a regional branch was established in Chicago to serve the Midwestern area through affiliated groups of hospitals and ophthalmological societies.

Details of the Eye Bank and its work can be secured from its Executive Director, Mrs. Henry Breckinridge, The Eye-Bank for Sight Restoration, Inc., 210 East 64th Street, New York 21.

UNITED MEDICAL SERVICE GROWS

The February *Bulletin* of United Medical Service (370 Lexington Ave., New York 17) indicates how its services have been snowballing in the two and one-half years of its existence. More than twice as many persons were covered at the end of 1946 as at the beginning of the year. Average number of

new enrollments per month was over 20,000, but in January, 1947, they were nearly 51,000. Figures of number and amount of bills paid tell the same story; 1946 monthly average number of bills paid was over 600, in January, 1947, over 1,500; in 1946 the average monthly amount paid was over \$36,000, in January, 1947, nearly \$86,000 was paid.

United Medical Service is a doctor's plan of voluntary medical insurance sponsored by the Medical Society of the State of New York.

WORTH ACQUIRING

Nutritional Charts—The 12th edition of *Nutritional Charts for Medical and Other Specialists* was recently announced by the Research Department of H. J. Heinz Company. It also announces *Nutritional Observatory*, published three times a year to keep users of charts informed with current developments in more detail than is shown in the charts. Apply to Nutritional Observatory, Department 2C, H. J. Heinz Co., Pittsburgh 12.

Youth Serves the Community—This is a plan for student volunteer service in Community agencies giving information on how to organize such a plan, with emphasis upon creative experience and training in citizenship for the young. Available from Community Chests and Councils, 155 East 47th Street, New York 17, N. Y.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

Bovine Mastitis—A Symposium—
Edited by Ralph B. Little, V.M.D., and Wayne N. Plastridge, Ph.D., New York: McGraw-Hill, 1946. 546 pp. Price, \$7.00.

This is a comprehensive, up-to-date review of our knowledge of this disease written by a group of specialists. These include Mack A. Emerson, Charles W. Turner, Lloyd B. Sholl, Leland J. Tompkins, Wayne N. Plastridge, Claude S. Bryan, Ralph B. Little, J. Howard Brown, Arthur W. Stableforth, Oscar W. Schalm, and Elmer O. Anderson. Discussions cover the anatomy of the udder and the physiology of milk secretion, as well as the diagnosis, bacteriology, pathology, serology, etiology, control, treatment, and, public health significance of this commonest of all cattle disorders that affect the quality of our milk supply.

Because of a literature that is too voluminous for anyone to study, even a specialist in this field, this book is timely and contains just the information that the public health worker needs. The problem of the control of this disease is not solved, but the problem is presented clearly and this presentation should in itself tend to direct observation and research into useful fields. Naturally streptococcal forms of mastitis are given the greatest amount of attention; but there is continuous recognition of other types of bacterial infections that cause other forms of mastitis, with the inclusion of a great amount of information that is not generally available.

The authors state on pages 179–181 that there is no conclusive evidence that a virus may be one of the predisposing causes of mastitis. However, in an

addendum to the book, Baker and Little of the Rockefeller Institute at Princeton report that they have at last recovered a virus-like agent from guinea pigs inoculated with bloody milk from lactating cows. They point out that the significance of this finding is not yet clear. All told, this is a stimulating and worth while book.

ROBERT S. BREED

Biochemistry of Cancer—By Jesse P. Greenstein. New York: Academic Press, 1947. 389 pp. Price, \$7.80.

Increased interest in all phases of experimental cancer has created a great need for up-to-date and critical technical treatises on that subject. This need, in so far as biochemistry is concerned, has been admirably filled by the timely appearance of this new publication. The book is prefaced by a chapter on the general phenomena and taxonomy of cancer. The first part deals with extrinsic and intrinsic factors involved in the induction of tumors; the second part deals with nutrition, endocrinology, and chemotherapy in attempts at control of tumor induction and tumor growth; the third part covers the chemistry of tumors, the chemistry of the tumor-bearing host, and the present status of the problem in relation to the properties of tumors. A comprehensive list of references for the work cited appears at the end of each chapter.

The author appears to have made no attempt at all-inclusiveness, but has carefully selected those topics for discussion which have met well established criteria for acceptance as scientific publications. The outstanding features of the book are the remarkable clarity of

presentation, the critical evaluation of the topics discussed, the excellent choice of subject matter and the inclusion of up-to-the-minute information on new research findings.

The book is highly technical and will find great use as a reference book and as a textbook for investigators in cancer research and students of medicine and related sciences.

LEONARD A. SCHEELE

Baby—A Mother's Manual—By Stella B. Applebaum. Chicago: Ziff-Davis Publishing Co., 1946. 118 pp. Price, \$2.50.

This is an attractive book, profusely illustrated and simply written. It attempts to cover the range of baby care from the prenatal period through the preschool age, adding a chapter on prevention and care of illness in the home. All this is attempted in 118 pages, with half of the book devoted to pictures rather than text. Because of the brevity of the book, the material is extremely telescoped, barely scratching the surface of some subjects. For instance, prenatal diet in its entirety is covered in one-half page.

In spite of this, the book seems to have certain values. The information is accurate as far as it goes and leads readers to want to learn more. There is a complete bibliography supplemented by direct references throughout the text, giving additional sources of information. Community agencies and their purposes are mentioned with their uses so that one would know where to turn for further help.

The attitude of the author toward the emotional tone in the family is particularly good. In an optimistic and taken for granted manner she explains how the parents' reactions to each other and the baby are important in keeping the baby secure and healthy.

There are many more detailed books available. However, this one would be

a good beginning for an intelligent couple who are willing to read further, because it is generally attractive and stresses good emotional attitudes.

IDA McROBERTS

Chemotherapeutic and Other Studies of Typhus—By M. Van den Ende, C. H. Stuart-Harris, F. Fulton, and J. S. F. Niven with C. H. Andrewes, A. M. Begg, W. J. Elford, M. H. Gleeson White, W. L. Hawley, K. C. Mills, F. Hamilton, and C. C. Thomas. Medical Research Council, Special Report Series 255, London, His Majesty's Stationery Office, 1946. 246 pp. Price, \$3.65.

This is a report of the results of studies of typhus fever made by members of the Medical Research Council staff at the National Institute for Medical Research, London, and by the British Army Typhus Research team during the recent war. Interest was concentrated in fields which were believed not under intensive study by the U. S. A. Typhus Commission and Canadian workers. The principal objective of the British investigations was the discovery of an effective chemotherapeutic agent.

In the preliminary screening, some 238 drugs, which are listed, were tested for activity against experimental typhus infection in mice. Two of the compounds, sulfonamides designated V147 and V186, which are *para*-sulphonamidobenzamidine hydrochloride and *para*-sulphonamidobenzamidoxime hydrochloride, respectively, were selected for special investigation, as they were found to have some effect upon the development of the disease in mice, although not when their administration was begun later than 42 hours after infection. Section I of this report describes the studies of the toxicity of these drugs for mice, guinea pigs, and human beings. The observations afforded only a very rough approximation to the maximum tolerated

dose, but serve as a guide to therapeutic trials. The second and principal section of this monograph deals with the clinical use of these drugs in the treatment of typhus infections in human beings. As is usual under war conditions, a great deal of difficulty was encountered in setting up satisfactory test and control groups of patients. Preliminary studies were carried out in North Africa. The 1943-1944 Naples epidemic, which is briefly described, afforded an admirable opportunity for more satisfactory chemotherapeutic trials. The final analysis was based on a series of 60 patients, of whom, 30 received either V186 or V147. Throughout the work no data as to the retention, blood-level or excretion of the drugs could be obtained, as no method of chemical estimation was available. On the basis of clinical severity, duration, and mortality, there appeared to be no significant difference between the treated group and the control group. The observation failed to establish the value of either drug in the treatment of epidemic typhus. In the course of these studies it became necessary to consider very carefully the diagnosis, prognosis, clinical manifestations, and pathology of typhus fever. These have been reviewed in some detail. Comparison with the clinical features of typhus as given by Murchison, 1884, indicates how little the disease has changed in the last 50 years.

Sections III, IV, and V contain accounts of laboratory investigations of typhus carried out at Hampstead. In Section III, a quantitative test for the neutralizing antibodies against rickettsiae is described. The method of assay depends upon intranasal inoculation of mice. Section IV presents a comparison of typhus vaccines by active immunization of experimental animals. It was concluded that vaccine potency depends upon the number of rickettsiae present, and is independent of the "soluble antigen." The authors also ex-

press the opinion that the power of the vaccine to protect mice against the "toxicity" of rickettsiae injected intravenously affords the most convenient and reliable test of vaccine potency. The fifth section is devoted to a comparison of the antigenic structure of a murine (Wilmington) strain of typhus rickettsiae with that of a strain (Cairo, Egypt, 1942) (judged to be identical with the Breinl strain) of epidemic typhus rickettsiae. It is concluded that the surface antigen of the murine strain is similar to, but not identical with, the surface antigen of the epidemic strain.

This monograph is one of the important documents dealing with medical research during the recent World War. It is a reference work which all investigators of the rickettsial diseases will desire to have in their libraries.

KENNETH F. MAXCY

The Human Body — By Clifford Lee Brownell and Jesse Feiring Williams. New York: American Book Company, 1946. 310 pp. Price, \$1.52.

This is a textbook on anatomy and physiology for upper grade school youngsters. Technical facts are simply stated and are subject to the usual errors of simplification so common to first editions. Collaboration with a physiologist would have been helpful. Perhaps junior high school children should not know that the human body has a reproductive system, since it is omitted in this text.

The anatomical diagrams are excellent and photographic cuts of youth activities may intrigue children. The hygiene content is incidental and will probably be either enlarged or deleted in future editions. "Questions and Problems for Discussion" and "Things to Do," which come at the end of each chapter, are good devices for busy teachers. A good glossary and subject index add to the value of the book.

CHARLES E. SHEPARD

The Freezing Preservation of Foods—By *Donald K. Tressler and Clifford F. Evers*. New York: *Avi Publishing Company* (2nd ed.). Revised and Enlarged, 1947. 932 pp. Price, \$10.00.

The 25 chapters of this handbook cover thoroughly the technology and science of frozen foods. Chapters of particular interest to public health workers deal with nutritive values, microbiology, changes occurring in preparation, freezing, storage, and thawing, and the importance of quality control and standards. Full directions for the preparation, freezing, and handling of fruits, fruit juices, poultry, meat, dairy products, fish and shellfish are included.

The importance of the frozen food locker industry is shown by the increase in number of plants in the United States to about 8,000 in 1946. The subjects of freezing equipment, principles of refrigeration, and packaging are adequately covered. The book is up-to-date. The numerous literature references at the end of each chapter make the book particularly useful for the student who desires source material or greater coverage on a particular subject. The 209 illustrations aid materially in clarifying the text and in making the book easy to read.

CARL R. FELLERS

Ground Water in the Baltimore Industrial Area—By *John C. Geyer*. Baltimore, Md.: *State Planning Commission*, 1945. Publication 44. 299 pp. Price, \$1.00.

This important and well prepared publication contains considerable information on the ground water resources of the Baltimore industrial area where about 40,000,000 gallons of ground water are pumped each day, chiefly from wells drilled in the Coastal Plain sediments of Cretaceous age. The pumpage of this large quantity of water, together with improper maintenance of wells, has caused several serious ground water problems. These are: contamination of

aquifers by salt and acid waters, decrease in yield of wells, decline in static water levels in wells, and loss of wells from structural failure of screens or casing.

The chief purpose of the publication is to analyze the cause of these problems and to present methods of correcting or preventing them. It also is intended to furnish a basis for further detailed studies. In addition to a detailed analysis of the ground water problems, the publication is well documented with several appendices containing a large amount of factual data, such as records of wells and well logs.

Although the occurrence of ground water in the Baltimore area is complex, the data and interpretations are presented so clearly that the reader should experience no difficulty in obtaining an understanding of the ground water conditions. The publication will be particularly valuable to the numerous establishments in the area that obtain their water supplies from ground water sources. It also will be of interest and value to all persons concerned with the development or study of ground water supplies in other areas.

ROBERT R. BENNETT

Health and Body Building—By *Frank Merrill Wheat and Elizabeth T. Fitzpatrick*. New York: *American Book Company*, 1947. 517 pp. Price, \$2.08.

This is a textbook prepared to meet the needs of high school pupils as outlined in the New York State Syllabus for Health Education. The book is conveniently divided into ten units, each headed by a positive statement, e.g., Unit IV—"To Function Efficiently your Body Parts must be in Excellent Health." Each unit is made up of chapters introduced by a question, e.g., "What are the Units and Larger Parts of Body Structure?" These chapters close with suggested things to do and some review questions which emphasize the principal points in the chapter.

The material is, as a whole, scientifically correct and is presented in a manner that is interesting to the adolescent and also may be challenging to those who wish to delve deeper. Emotional appeal is, rightly, almost absent but the appeal of fear is somewhat overused, as is the reference to World Wars I and II. As these events move into the background the references will have less meaning.

Building of character and useful, happy lives has been brought out very well by units on personal health and appearance, mental health and behavior, and community living. The content regarding the anatomy of body systems—digestive, circulatory, musculature, etc.—is covered quite completely, but that of the reproductive system has been left out. This omission was undoubtedly intentional, as many schools will not allow sex education.

This book is more than merely informative of basic scientific facts. It is constructive. It encourages the use of these facts to build "happy, resourceful, productive lives." If but one textbook can be used by pupils, this one appears to be very appropriate.

CATHARINA HUNTSMAN

Harvey Cushing: A Biography—
By John F. Fulton. Springfield, Ill.: Thomas, 754 pp. 150 illus. Price, \$5.00.

Here is a first rate biography of a distinguished surgeon whose professional life was spent at Hopkins, Harvard, and Yale. Written by Dr. John F. Fulton, Sterling Professor of Physiology at Yale, the style is reminiscent of that which Cushing set for his life of William Osler.

Although Cushing was a neurological surgeon, his influence was a wide one and such fields as endocrinology and the history of medicine were greatly enriched by his contributions. In later life he took an interest in the field of social medicine and lent his influence to the

study of public medical care and health insurance. He advocated a type of federal organization for public health like that currently proposed in Congress.

For those who fell under Cushing's influence this book is not to be missed. For all it portrays the life of a great doctor in fascinating style.

REGINALD M. ATWATER

Radio—How, When and Why to Use It—
By Beatrice K. Tolleris. New York: Russell Sage Foundation, 1946. 46 pp. Price, \$1.00.

In 46 fact packed pages, this booklet analyzes and offers sound solutions to the problems faced by health, welfare, and community organizations who want to reach the radio public.

Knowledge acquired by painful trial and error methods through years of educational broadcasting by organizations throughout the country is assembled here. As a standard textbook on radio broadcasting for non-profit agencies, it belongs in the reference library of every organization that is using or planning to use radio in its public relations program.

A guide to the organization that is just embarking upon the use of radio media, it is also a check list against which agencies can test the effectiveness of their existing programs.

In six readable sections, interspersed with enlightening examples taken from current programs, the booklet discusses points to be considered in deciding whether radio is the medium needed. It describes the various types of program formats, the purpose each serves, and how to use them effectively. It points up the advantages and disadvantages of joining with other organizations in coöperative broadcasts and in securing guest time on existing local and network programs. It offers suggestions for getting time on the air, for maintaining mutually beneficial relations with

the radio stations, and for building up the audience you want to reach.

JEAN HENDERSON

Vitamins and Hormones—Advances in Research and Applications, Vol. IV. Edited by Robert S. Harris and Kenneth V. Thimann. New York: Academic Press, 1946. 406 pp. Price, \$7.00.

The excellence of the fourth volume of this series indicates that there is sufficient progress in the field of vitamins and hormones to warrant yearly reviews, and that the editors are able to obtain capable contributors. It is immediately evident to the reader, and the editors comment on the fact, that three chapters in the volume deal specifically with interrelationships between nutrition and hormones: Effect of B Vitamins on the Endocrinological Aspects of Reproduction, by Hertz; Nutritional Therapy of Endocrine Disturbances, by Biskind; and the Protein Anabolic Effects of

Steroid Hormones, by Kochakian. The first three chapters should be especially valuable to public health workers. Pfiffner and Hogan present a very readable and yet thoroughly complete summary of The Newer Hematopoietic Factors of the Vitamin B-Complex. Regardless of all additional knowledge which must of necessity become available with further work, the chapter on Nutrition and Resistance to Infection will remain a classic in this field. The chapter by Clements on Manifestations of Nutritional Deficiency in Infants will be very useful, although the subject is presented in a textbook form rather than as a critical review of recent research. The remaining chapters include timely subjects reviewed by well known workers in each of the fields: The Thyroid and Diabetes, by Houssay; Thyroactive Iodinated Proteins, by Reineke; and Methods of Bioassay of Animal Hormones, by Thayer.

C. A. ELVEHJEM

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

A CASE WORK APPROACH TO SEX DELINQUENTS. Rosa Wessel. Editor. Philadelphia: Pennsylvania School of Social Work, 1947. 132 pp. Price, \$1.50.

THE HEALTH EXAMINATION (rev. ed.). New York: Community Service Society, 1947. 42 pp.

MALARIA CONTROL ACTIVITIES IN GREECE DURING 1946 (mimeo.). By Dr. Gr. A. Livadas and Dr. George D. Belice. Athens, 1946. 22 pp.

NURSING FOR COMMUNITY HEALTH. By Theda L. Waterman, R.N. (2nd ed.) Philadelphia: Davis, 1947. 421 pp. Price, \$3.50.

NUTRITIONAL AND VITAMIN THERAPY IN GENERAL PRACTICE. By Edgar S. Gordon, M.D. (3rd ed.) Chicago: Year Book Publishers, Inc., 1947. 410 pp. Price, \$5.00.

PENICILLIN THERAPY. By John A. Kolmer, M.D. (2nd ed.) New York: Appleton-Century, 1947. 339 pp. Price, \$6.00.

PROCEEDINGS OF THE NATIONAL CONFERENCE OF SOCIAL WORK. New York: Columbia University Press, 1947. 608 pp. Price, \$5.00.

TOMORROW'S FOOD. By James Rorty and N. Philip Norman, M.D. New York: Prentice-Hall, Inc., 1947. 258 pp. Price, \$3.50.

VETERINARY BACTERIOLOGY. By I. A. Merchant. (3rd ed.) Ames, Iowa: Iowa State College Press, 1946. 683 pp. Price, \$7.00.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Good News for Young Mothers— Research in the prophylactic possibilities of gamma globulin yields the following findings: if given within 6 days of exposure it prevents measles 4 times out of 5 and modifies the infection in almost all other cases; given early, and in hefty doses it reduces the case incidence of infectious hepatitis; it seems likely that it may help against scarlet fever, but not against poliomyelitis, chickenpox, or infantile diarrhea. When processed from convalescent plasma, the homologous globulin is effective against mumps and whooping cough.

BERENBERG, W. Gamma Globulin as a Prophylactic and Therapeutic Agent in Communicable Disease. *Milbank Quart.* 25, 2:115 (Apr.), 1947.

Experience Is Essential to Knowledge—“Words are not tools for teaching nutrition.” I’m tempted to let the quote stand alone as the annotation for this stimulating discussion. I’ve decided I will, for if it doesn’t tease you into hunting out the paper, nothing will.

BOSELY, B. A Practical Approach to Nutrition Education for Children. *J. Am. Dietet. A.* 23, 4:304 (Apr.), 1947.

Remember Typhoid Mary?—Seems like old times to run across a lecture on typhoid carriers. This senior officer from the British Ministry of Health rather ponderously declares that carriers may be found by resourceful detective work, involved bacteriologic techniques, and teamwork by experts in the field.

BRADLEY, W. H. Methods Adopted in the Detection of “The Carrier.” *J. Roy. Inst. Pub. Health & Hyg.* 10, 3:86 (Mar.), 1947.

“Have a Health Examination.”—Among the lessons learned from six hard and lean years of promoting prepaid

medical care plans is this one: thorough physical examinations and (except by hypochondriacs) medical consultation on general conditions of health are *not* sought by patients. Those of us who prate about semi-annual physical examinations after 40 as the solution to the cancer problem should digest this bit of gristle.

CARLTON, W. The Problem of Social Medicine: Equilibrating the Distribution and Technology of Medical Care. *New England J. Med.* 236, 14:493 (Apr. 3), 1947.

Richettsias Condensed —Reduced to practical details, this discussion of the rickettsial diseases and their vectors is addressed to nurses but it is just as appropriate for inspectors or medical social workers or whatever specialty in the public health field you happen to be pursuing.

DYER, R. E. What the Public Health Nurse Needs to Know about Rickettsial Diseases. *Pub. Health Nurs.* 39, 3:124 (Mar.), 1947.

Booster Doses, the Answer—Virulent diphtheria swept through a girls’ school (British) in which 94 per cent of the children had been immunized and 80 per cent were found Schick-negative. Ruefully concludes the reporter, even a highly immunized community is not entirely safe. Don’t you love the “entirely” understatement? In following papers two other doctors (from Belgium and India) report upon penicillin in the treatment of diphtheria.

FANNING, J. An Outbreak of Diphtheria in a Highly Immunized Community (and two related papers). *Brit. M. J.* 4498:371 (Mar. 22), 1947.

Rheumatic Fever Follows Strep Epidemics—Two per cent of all school children in the United States have heart disease as a result of rheumatic fever.

This is the first of many accusations directed at the worst of the enemies of childhood. Every youngster with a streptococcal throat infection is a potential rheumatic fever subject, says this writer, who tells what to do about it.

GRIFFITH, G. C. Rheumatic Fever. *J.A.M.A.* 133, 14:975 (Apr. 5), 1947.

One for Air Sterilization—Contagion due to contact between patients cannot be prevented by ultraviolet air sterilization, say these researchers, but the lights do prevent air-borne distant spread of infection and—for custodial institutions—the cost is justified.

HIGGINS, R. A., and HYDE, G. M. Effect of Ultraviolet Air Sterilization upon Incidence of Respiratory Infections in a Children's Institution. *New York State J. Med.* 47, 7:707 (Apr. 1), 1947.

Science Leavened with Common Sense—"And the School Nurse" might have been omitted from the title of this brief review of recent findings in child development and new-day trends in child care, for it is a useful paper for all who have anything to do with the health of youngsters.

HILDRETH, G. Child Development and the School Nurse. *Pub. Health Nurs.* 39, 4:181 (Apr.), 1947.

Mind Over Matter—Steel workers were divided into three groups: one received vitamin pills, the second placebos, the third nothing. Later the groups were reversed. There was no indication that the vitamins had any measurable effect. Absenteeism due to illness was lowest in the placebo group. There was less *voluntary* absenteeism in both vitamin and placebo groups than in the pill-less third.

IVY, A. C., *et al.* The Effect of Administering a Vitamin Supplement, in Capsules, to Groups of Workers in a Steel Industry. *Indust. Med.* 16, 4:163 (Apr.), 1947.

Working at Pertussis Prevention—Presented here is convincing evidence

that both the morbidity and mortality rates of whooping cough are lowerable by community vaccination programs. Booster doses of combined whooping cough and diphtheria antigen are needed at school entrance, for then the child meets increased exposure to both diseases.

KANDLE, R. P. The Control of Whooping Cough. *Pub. Health News* (New Jersey State Department of Health). 28, 8:229 (Apr.), 1947.

Seasons and Polio—Does poliomyelitis virus persist in urban sewage all the time? If it does would this fact seem to suggest that outbreaks are due to lowering of human resistance at certain seasons? Well, with the most sensitive methods at his command, this researcher could recover virus from sewage only in epidemic years and then only in late summer and early fall. It cannot be concluded from his study that the nature of epidemics is due to seasonal variation in host susceptibility.

MILNICK, J. L. Poliomyelitis Virus in Urban Sewage in Epidemic and Nonepidemic Times. *Am. J. Hyg.* 45, 2:240 (Mar.), 1947.

Bricks Without Straw—Administrators who are hard up now for doctors to staff their agencies or institutions will find little comfort in the Surgeon General's prophesy that, if present training programs are not enlarged, we shall be short 30,000 doctors by 1960. The number of dentists needed, and not being trained, verges on the astronomical. When it comes to future shortages of nurses, the S. G.'s prophetic powers fail him.

PARRAN, T. Hospitals and the Health of the People. *J.A.M.A.* 133, 15:1047 (Apr. 12), 1947.

Big Job Well Done—Ninety-five doctors, nurses, dentists and dental hygienists work a full school day to improve the health of 116,000 Pittsburgh school children and this service costs \$2.70 per child. If you are interested.

you will find¹ the working plan outlined for your benefit.

SMITH, L. M. Health Service in the Pittsburgh Schools. *J. School Health*. 17, 4:95 (Apr.), 1947.

Problems of Out-and In-Migration
—Though our farm population increased by more than 1¼ millions in two recent years it was still smaller, by 11 per cent, than in 1940, and smaller than it had ever been in the last fifty years. Though a severe depression might boost farm in-migrations, it is not likely otherwise that we shall ever again see so large a part of all Americans living on farms as in 1940. This phenomenon

has many social and hygienic implications. Does it have any bearing on your future job?

TAEUBER, C. Recent Trends of Rural-Urban Migration in the United States. *Milbank Quart.* 25, 2:203 (Apr.), 1947.

"So High and Mighty"—What pregnant women worry about and how public health nurses can help in this mental hygiene problem are discussed here. We need more practical papers like this. One guided mother-to-be characterized her guide with the quotation above.

ZIMMERMAN, K. A. The Public Health Nurse and the Emotions of Pregnancy. *Pub. Health Nurs.* 39, 2:63 (Feb.), 1947.

ASSOCIATION NEWS

VOCATIONAL COUNSELING AND PLACEMENT

The Association's Vocational Counseling and Placement Service frequently receives inquiries from weary employers who have been struggling without sufficient personnel. The question generally asked is: "What percentage of the vacancies now existing for physicians, nurses, engineers, and other professional groups can be expected to be filled this year, next year, by 1950?"

The accredited schools of public health in the United States have increased their enrollment considerably during the academic year just ending. According to preliminary figures compiled by the U. S. Public Health Service, the graduate student enrollment was 63 per cent higher during 1946-1947 than during the academic year 1945-1946. The total number of graduate students from the United States and the Territories was 521. Of these, 155 were physicians, 137 health educators, 41 engineers, 53 laboratory workers, 27 statisticians, 37 nurses, and the remaining students were representatives of other professional groups. Among the native students, at least 56 per cent were already committed to an employer at the time they entered school. According to information at hand, many of the remaining 44 per cent had already found employment for the end of the current school year.

It is difficult to estimate how long it would take to fill existing vacancies at the present rate of training since there are no recent overall figures available. The statistics of the Vocational Counseling and Placement Service of the American Public Health Association offer a representative picture, although

not a complete one. At the last count, a total of 738 openings was registered as against a total of 157 candidates for positions. Among the openings, 408 were for physicians (at least one-fourth requiring an M.P.H. degree). This means that it would take almost the total enrollment of physicians in schools of public health in 1946-1947 to fill only the vacancies requiring an M.D. and an M.P.H. degree as known to the Vocational Counseling and Placement Service. The statistics of this Service reflect the same discrepancies of demand and supply for public health engineers, trained health educators, and statisticians.

A large number of openings still exists in the field of public health nursing. A recent survey of nursing needs in public health agencies conducted by the U. S. Public Health Service reveals that the total number of vacancies expected on July 1, 1947, will approximate 3,500. This figure exceeds the full-time enrollment of nurses at schools of public health nursing and schools of public health.

A consideration of the enrollment at schools of public health, public health engineering, and public health nursing would not give a complete picture of personnel resources since most agencies, as part of their recruitment efforts, will accept newcomers without a public health degree, planning to send them to school at a later date. It is difficult to evaluate at this point how effective recruitment measures conducted by various official and voluntary agencies have been. The American Public Health Association's Vocational Counseling and Placement Service has taken every opportunity to recruit personnel. It was

first established in the fall of 1945 as a cooperative project of the U. S. Public Health Service and the A.P.H.A. One of its prime objectives was to attract to the public health field men and women who received pertinent training and experience in the armed forces. Recruitment is carried on primarily through counseling on an individual basis. In addition, talks to groups of college students, conferences with counselors in related agencies, and other

collective measures, such as publication and distribution of vocational booklets, are parts of the program.

Low salaries are only part of the explanation for our present shortage of personnel. The advantages of careers in the field of public health are not sufficiently known to young people deciding upon their future vocation. The gap can be closed through efficient and energetic recruitment wherever and whenever possible.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

John A. Bargcr, M.D., Municipal Courts Bldg., Room 19, St. Louis 3, Mo., Supervisor, Venereal Disease Control Service, City Health Dept.
 Bernard Bucove, M.D., D.P.H., Medical Health Officer, Weyburn, Saskatchewan, Canada
 Newman H. Dyer, M.D., 101 50th St., S.E., Charleston, W. Va., State Health Commissioner
 James A. Fields, M.D., Health Dept., South Boston, Va., Health Officer
 William H. Handel, M.D., 134 W. Eagle St., Buffalo 2, N. Y., Medical Director, Erie County Health Dept.
 Vincent H. Handy, M.D., M.P.H., 374 Delaware Ave., Buffalo, N. Y., Asst. District Health Officer, State Health Dept.
 John J. Hanson, Health Dept., City Hall, New Brunswick, N. J., Health Officer
 Noka B. Hon, M.D., U. S. Public Health Service, Bethesda, Md., Asst. Chief, States Relations Division
 Gerald L. Infield, M.D., 707 Shore Road, Northfield, N. J., City Health Officer
 Samuel C. Ingraham, II, M.D., M.P.H., State Planters Bank Bldg., Richmond, Va., Surgeon, U. S. Public Health Service District No. 2
 Lt. Col. Paul H. Leach, M.C., 615 N. Wolfe St., Baltimore, Md., Student, School of Hygiene and Public Health, Johns Hopkins Univ.
 Herbert L. Mantz, M.D., 618 Professional Bldg., Kansas City, Mo., Tuberculosis Controller, City Health Dept.

Byron O. Mork, Jr., M.D., Worthington Clinic, Worthington, Minn., Chairman, County Public Health Nursing Committee
 Andrew W. Orlowski, M.D., 19 Mason St., Torrington, Conn., City Health Officer
 Jorge Quinteros C., M.D., Calle Mexico No. 152, La Paz, Bolivia, S. A., Director, Dept. of Venereal Diseases, Cooperative Service of Public Health
 Leo Schnur, M.D., Pima Indian Reservation, Sacaton, Ariz., Senior Physician, Office of Indian Affairs
 Tito Lopes da Silva, M.D., Rua Guadalupe 725, Sao Paulo, Brazil, S. A., Public Health Officer, Sao Paulo State Public Health Dept.
 Louis B. Thomas, M.D., Idaho Rapid Treatment Center, Box 2637, Boise, Ida., Asst. Surgeon (R), U. S. Public Health Service
 Eugene Walker, M.D., C.M., 759 Chestnut St., Springfield 7, Mass., Supt., The Springfield Hospital
 Robert L. Zobel, M.D., M.P.H., 603 State Planters Bank Bldg., Richmond, Va., Surgeon, U. S. Public Health Service

Laboratory Section

Edward H. Armbruster, M.S., School of Public Health, Univ. of Michigan, Ann Arbor, Mich., Research Assoc. in Public Health Engineering
 Laurice Bailey, 741 Culbertson Drive, Oklahoma City, Okla., Laboratory Technician, State Dept. of Health
 Ernest J. Barnard, 827 W. Maple St., Johnson City, Tenn., Director, Johnson City Branch Laboratory, State Health Dept.
 Eva G. Bernhardt, M.S., 1 Agnew St., Montgomery 6, Ala., Junior Bacteriologist,

Division of Laboratories, State Dept. of Health

Mildred F. Claiborne, 1812 McClung St., Charleston, W. Va., Acting Supervisor, Water and Milk Division, State Hygienic Laboratory

Maryann E. Coulson, 14356 Greenleaf St., Sherman Oaks, Calif., Laboratory Asst. Veterans Administration

Herald R. Cox, ScD., Lederle Laboratories, American Cyanamid Co., Pearl River, N. Y., Director of Viral and Rickettsial Research

Sidney J. Coyne, 1140 South Michigan Blvd., Chicago 5, Ill., Director, Enoz Research Laboratory

Deane C. Epler, M.D., Bozeman, Mont.

Carlos de la V. Espana, M.S., Hooper Foundation, Univ. of Calif., Medical Center, San Francisco 22, Calif., Fellow, National Foundation for Infantile Paralysis

Dale O. Galloway, Chilhowee Drive, Rt. 6, Knoxville, Tenn., Student, Univ. of Tennessee

Jesshill Love, M.D., 509 Brown Bldg., Louisville, Ky., Director, Cancer Clinic

Solomon M. Michaelson, D.V.M., 1967 81st St., Brooklyn, N. Y., Laboratory Asst., City Dept. of Health

Richard C. Montgomery, M.S., State Health Dept., Hagerstown, Md., Assoc. Bacteriologist, State Dept. of Health

Esther L. Morgan, Box 209, Flagstaff, Ariz., Senior Bacteriologist, State Dept. of Health

Richard A. Morrissey, M.P.H., State Dept. of Public Health, Div. of Labs., Springfield, Ill., Bacteriologist

John L. Neal, 1800 West Fillmore, Chicago, Ill., Immunologist, State Dept. of Public Health

Joseph Portnoy, M.S., Pan-American Sanitary Bureau, Apt. 383, Guatemala City, Guatemala, C. A., Assoc. Serologist, Venereal Disease Research Laboratory

Arthur H. Razee, 131 West St., Mansfield, Mass., Manager, Chemical Service, Rumford Chemical Works, Rumford, R. I.

Ethel M. Schuler, 333 E. 16th Ave., Denver, Colo., Chemist, City Health Dept.

Juan Talavera, D.V.M., Calle Iturbe, 14, Madrid, Spain, Inspector Veterinarian, Direccion General Ganaderia

Tien-hsing Yieh, M.D., D.P.H., 90 Church St., New York, N. Y., Bacteriologist, First Army Laboratory

ington, D. C., Medical Research Officer, Veterans Administration

Jesse B. Lasater, 4941 Arsenal St., St. Louis 9, Mo., Registrar, Bureau of Vital Statistics, Division of Health

Marinus G. Neurdenburg, M.D., D.P.H., Frans van Mierisstraat 134, Amsterdam Zuid 1, Holland, Public Health Officer and Chief of Statistics, Municipal Medical and Public Health Service

Engineering Section

Jose Arrisueno, 362 Bellavista, Miraflores, Lima, Peru, S. A., Student, Harvard University, School of Engineering

Max L. Barrett, 1700 N. Harrison St., Fort Wayne, Ind., Sanitary Engineer, State Board of Health

Edward M. Bivins, 559 Pacific St., Monterey, Calif., Sanitarian, Bureau of Sanitation, State Dept. of Public Health

Ross W. Buck, 605 Volunteer Bldg., Atlanta, Ga., S. A. Engineer (R), Training Division, Typhus Fever and Rodent Control, U. S. Public Health Service

Hernando Correal, 611 Church St., Ann Arbor, Mich., Student, School of Public Health, Univ. of Michigan

Edgar E. Diddams, M.S.P.H., City Hall Annex, Tacoma, Wash., Chief, Division of Sanitation, City Health Dept.

Ernest P. Dubuque, 2306 Westminster Way, N.E., Atlanta 6, Ga., S. A. Engineer (R), In charge of In-service Training, U. S. Public Health Service, Communicable Disease Center

Urano C. Eichenberg, M.P.H., Rua Hoffmann 740, Porto Alegre, R.G.S., Brazil, S. A., Student, School of Public Health, Univ. of Michigan

Roy F. Fritz, M.S., 605 Volunteer Bldg., Atlanta, Ga., Entomologist, Typhus Branch, Communicable Disease Center, U. S. Public Health Service

Harold S. Griswold, 400½ East Vantrees St., Washington, Ind., Sanitary Engineer, State Board of Health

Nathan I. Kass, 167 Beaumont St., Brooklyn 29, N. Y., Sanitary Engineer, Dept. of Public Works

Philip H. Kime, Princess Anne, Va., Sanitation Officer, State Health Dept.

LaRue L. Miller, State Dept. of Health, Bureau of Eng., Lansing 4, Mich., Chief, Division of Environmental Sanitation

Floyd A. Reese, 702 Municipal Bldg., Akron, Ohio, Director of Sanitation, City Dept. of Health

Rudolph C. Rosine, 156 Walnut Ave., Galesburg, Ill., Sanitarian, Division of Sanitary

Vital Statistics Section

Benjamin L. Gotham, M.A., Box 932, U. S. Public Health Service, Pharr, Tex., Field Statistician, Communicable Disease Center

Lee Jarvis, M.S., 2619 42nd St., N.W., Wash-

Engineering, State Dept. of Public Health
Claude R. Stonchouse, 1729 Hampshire Rd.,
Victoria, B. C., Canada, Senior Sanitarian,
Provincial Health Dept.

Clifford N. Stutz, M.S., 1009 N. Park St.,
Bloomington, Ill., Sanitary Engineer,
McLean County Health Dept.

E. A. Turner, P. H. and W-Sec., G.H.Q.-SCAP,
APO 500, San Francisco, Calif., Sanitary
Engineer Consultant to Chief of Public
Health and Welfare Section

Mario R. Valdes P., 309 E. Catherine, Ann
Arbor, Mich., Student, School of Public
Health, Univ. of Michigan

Industrial Hygiene Section

CLOSING DATE FOR SUBMISSION OF FELLOWSHIP APPLICATIONS

August 1 will be the last date on which Fellowship applications can be accepted for consideration at the 1947 Annual Meeting in Atlantic City.

Eligible members who wish to apply for Fellowship this year are therefore urged to send in their applications as early as possible.

ERRATA TO NINTH EDITION OF THE STANDARD METHODS FOR THE EXAMINATION OF WATER AND SEWAGE

The following corrections are called to the attention of anyone using the Ninth Edition of the Standard Methods for the Examination of Water and Sewage:

1. Page 24 Sec. 10, B, 1.6. The formula for determining the reagent value of potassium palmitate should read: Mg. CaCO_3 per ml. potassium palmitate = ml. standard calcium chloride soln \div ml. potassium palmitate soln.

2. Page 54 Sec. 24, D, 3, line 6 should read: To about 40 ml., add 5 ml. of 3 N HCl. . . .

3. Page 216 Appendix I, left column, Sec. 4, 3, line 31, sentence should read: Copper does not interfere below 0.2 ppm. (Delete the words "the maximum limit permissible accord-

ing to the 'Drinking Water Standards' of the U. S. Treasury Dept.")

The above corrections concern the only errors appearing in the Ninth Edition that have been called to the attention of the editorial staff. Members of the Association and users of the Methods are requested to transmit a record of any other errors discovered to:

REGINALD M. ATWATER, M.D.

Executive Secretary,

American Public Health Association

A MESSAGE FROM THE CIRCULATION
DEPARTMENT

Because public health workers are notoriously frequent movers hundreds of changes of address are reported to the Circulation Department each month. These changes are recorded promptly. Occasionally, however, a member will write in complaining about non-receipt of *Journals* and report for the first time a new address which has been in effect for several months.

New address notifications received

before the 15th of the month will catch the next issue of the *Journal*. Those received between the 15th and the end of the month will be made with the *Journal* published the month after the next. It will assist the Circulation Department and benefit the individual member if address changes are reported to the Association a month in advance.

Members are also urged to notify their post offices of their new address when they move and to instruct that mail be forwarded.

Opportunities Wanted

Physician well trained in public health and experienced in student health work; A.B., M.A., and M.D. degrees leading schools; graduate training in public health; several years' teaching experience; five years, director of student health service during military leave of permanent director; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Young dentist desires position involving some aspect of public health dentistry; institution; A.B. and D.D.S. degrees, midwestern universities; three years in the Navy, now in private practice; will go anywhere; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Bacteriologist; M.S., Ph.D. degrees, eastern university; six years' teaching experience; six years, bacteriologist, public health organization; has assisted in research and editorial work; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Health educator; M.S. degree in health education; doctor of education degree (major in School Health Education); eight years on staff, state university in department of health education; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Sanitary engineer; bachelor of science in civil engineering; master's degree in public health engineering; since 1940, sanitary engineer with county department of health and part-time teaching (public health) in university; seeks greater responsibilities; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Public health nurse; graduate of five year public health nursing course; B.S. degree; three years, general staff nurse, rural public health nursing program; scholarship to study health education; Master's degree in health education; eight years' important administrative experience in public health; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

U. S. REGULAR ARMY CORPS RECRUITS FORMER OFFICERS AS CLINICAL PSYCHOLOGISTS AND PSYCHIATRIC SOCIAL WORKERS

Clinical psychologists and psychiatric social workers are needed in the U. S. Army. Former officers of the U. S. Army may now apply for commission in the Pharmacy Corps as technical specialists. College graduates with a degree acceptable to the Surgeon General which will basically qualify the officer for further training in clinical psychology and psychiatric social work respectively, will be acceptable for integration into the Pharmacy Corps. Minimum requirements for psychologists include civilian experience in abnormal or clinical psychological practice and a Master's degree in psychology (specialization in clinical, educational or industrial psychology). Minimum requirements for psychiatric social workers include at least one year's study in an accredited school of social work inclusive supervised field work plus one year's acceptable social case work experience.

Closing date for applications: July 31, 1947. For further information and application blanks write to Neuropsychiatry Consultants Division, Office of the Surgeon General, War Department, Washington 25, D. C.

NEWS FROM THE FIELD

UNIVERSITY COURSES IN HOSPITAL ADMINISTRATION

Announcement has recently been made of courses in hospital administration in three additional universities—University of Iowa, Washington University, and Yale University. The latter two are made possible by the collaboration of the W. K. Kellogg Foundation.

The University of Iowa program in hospital administration will be made up of two phases, an administrative internship and an administrative residency, each lasting from six to eighteen months. The program was begun on February 1, 1947. It will lead to a Master's or Doctor's degree in hospital administration.

The Washington University graduate course in St. Louis was established in September, 1946. It is a 21 month course made up of 9 months of academic instruction and 12 months of administrative internship in an approved hospital. The course is being given by the Department of Hospital Administration in the Division of Auxiliary Medical Services of the School of Medicine.

The Yale University program is announced for September, 1947, and will be given in the Department of Public Health of the School of Medicine. Its projected 21 months of training will be divided between academic residence at the university and administrative internship at a hospital. The program will lead to a Master's degree in hospital administration.

DR. SOPER HEADS PAN AMERICAN SANITARY BUREAU

On February 1, Fred L. Soper, M.D., assumed the position of Director of the Pan American Sanitary Bureau, Washington, D. C. He succeeds Surgeon

General Hugh S. Cumming (Rtd.), U. S. Public Health Service, who becomes Director Emeritus after 26 years of service.

Dr. Soper has most recently been Associate Director of the International Health Division of the Rockefeller Foundation. He served for 10 years (1930–1940) as Director of the Yellow Fever Service of Brazil. Here he organized and administered mass eradication campaigns against *Aedes aegypti* so successfully that by the end of 1933 a number of the principal ports of Brazil were completely free of this carrier of yellow fever. The same methods were later applied to other South American countries.

In June, 1944, Dr. Soper organized the Gambiae Eradication Service in Egypt. Nine months later the gambiae mosquito, which had been causing the most serious epidemic of malaria recorded in Egyptian history, was eradicated. For his work in the eradication of tropical diseases he received a Lasker award at the 1946 annual meeting of the Association in Cleveland.

During the late war Dr. Soper was engaged in typhus and malaria control in the Mediterranean area with the U. S. Typhus Commission and the Allied Military Control, among other agencies.

ADVANCED COURSE IN INDUSTRIAL HYGIENE NURSING AT COLUMBIA SCHOOL OF PUBLIC HEALTH

A new course in industrial nursing, leading to the M.S. degree in industrial hygiene, will be inaugurated in September, 1947, at the Columbia University School of Public Health (formerly DeLamar Institute) in New York. Applicants must be graduates of an ac-

credited school of nursing, have a baccalaureate degree, and must have had satisfactory experience in nursing.

The program includes industrial medical organization, occupational diseases and advanced industrial nursing practice, communicable diseases, health education, nutrition, public health practice, vital statistics, epidemiology, and field work in industry and community agencies. The course is one academic or one calendar year in length, depending on previous experience and preparation.

Senior Assistant Nurse Officer Emily M. Smith, U.S.P.H.S., will teach the industrial nursing courses. She has had experience in public health and industrial nursing and was most recently assigned to the Bureau of Industrial Hygiene of the Detroit City Department of Health.

This course for industrial nurses is a part of the generally expanded teaching program in industrial hygiene which has been established at the Columbia School of Public Health. Parallel curricula for physicians, engineers, and chemists are also being offered.

PROFESSOR WINSLOW HONORED AT YALE

On April 17, the 50th anniversary of Professor C.-E. A. Winslow's first publications, he was honored at a dinner at the New Haven (Conn.) Lawn Club by 150 faculty associates and graduates of the Yale Department of Public Health. Professor Winslow, who is an internationally known leader in public health, is Professor Emeritus of Public Health at Yale. He organized the Department of Public Health in 1915, serving as its chairman for 30 years until 1945.

Speakers at the dinner were, Dr. Hugh R. Leavell, Professor of Public Health Practices at Harvard, who represented the Yale Department's graduates; Dean Francis G. Blake of the Yale School of Medicine; Dr. George B. Darling, Director of Medical Affairs; and Dr. Mil-

ton Winternitz, Professor of Pathology.

Professor Winslow was presented with the first copy of the *March Yale Journal of Biology and Medicine* devoted entirely to 39 papers by his former students and colleagues, as well as a bibliography of 574 titles of articles, reports, and books written by Professor Winslow during the past 50 years. Among other contributors to this "Winslow" issue are the chiefs of the national health services of both the United States and Great Britain, Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service, and Sir Wilson Jameson, Chief Medical Director of the British Ministry of Health.

Another highlight of the dinner was the announcement of a Lectureship Fund in honor of Professor Winslow. To be known as the Winslow Public Health Seminar Fund, this will provide for outstanding visiting lecturers and leaders of public health seminars. The fund is being raised through contributions of associates and former students.

NEW LIGHT ON ARTERIOSCLEROSIS

Experiments in Goldwater Memorial Hospital, the chronic disease hospital of New York City Department of Hospitals, have succeeded in producing arteriosclerosis in dogs, according to a recent report. The research, carried on by Alfred Steiner, M.D., and Forrest Kendall, M.D., was supported in part by the Albert and Mary Lasker Foundation. It is expected to produce significant results in the treatment of arteriosclerosis in man to which that produced in dogs by the experiment bears a striking resemblance. The experiments are to be reported in a forthcoming issue of the *Archives of Pathology*.

NUCLEAR RESEARCH FOR MEDICAL AND PUBLIC HEALTH WORK

Joint plans of the U. S. Bureau of Standards and the U. S. Public Health

Service for a 20 million dollar national radiation institution at Bethesda, Md., have been announced by Leon F. Curtiss, chief of the radioactivity section of the Bureau of Standards. The institute would concentrate on research in radioactivity, radiobiology, and nuclear energy in general for protection of health. It would include large laboratories and a uranium pile valued at 3 million dollars. The project has been recommended by the President's Atomic Energy Commission but will require approval of Congress before it can be undertaken.

AUSTEN RIGGS FOUNDATION

The Austen Riggs Foundation, Inc. of Stockbridge, Mass., announces the appointment of Robert P. Knight, M.D., as Medical Director to assume his duties on September 1, 1947. Dr. Knight is at present Chief of Staff of the Menninger Clinic at Topeka, Kan., where he has served in various capacities since 1933.

At the same time the Foundation announced the appointment of Edgerton McC. Howard, M.D., as Associate Medical Director. He has been serving as Acting Medical Director.

The Austen Riggs Foundation was founded in 1919 by the late Dr. Austen Fox Riggs for the treatment, study, and training in therapeutic procedures of the psychoneuroses.

FIELD TRAINING FELLOWSHIPS

For several years the W. K. Kellogg Foundation has encouraged field training of engineers by the formation of county training areas in Michigan. According to a recent announcement of the Michigan Department of Health, an agreement between the W. K. Kellogg Foundation and the Michigan State Department of Health places future administrative responsibility for these training programs with the State Department of Health.

Under the present arrangement undergraduates will be accepted for training periods up to three months in length. Graduates may be accepted for a period as long as twelve months. A stipend of \$100 per month is paid the undergraduate; \$125 per month is paid the graduate trainee.

To be eligible for a fellowship the undergraduate must be a candidate for a degree "in one of the branches of public health (public health or sanitary engineering, dairy science, food technology, bacteriology, etc.)" in a recognized professional school. He must have completed his junior year. Graduates must have received a degree in one of the specialties mentioned above. There is no implied obligation on the part of the trainee or the Michigan State Department of Health in the matter of employment following completion of the training periods.

Inquiries should be sent to the Michigan State Department of Health, Lansing 4, Mich.

NEW MEDICAL CENTER FOR EL PASO

Following a recommendation of the U. S. Public Health Service and the Texas Hospital Service, a medical center is under construction in El Paso, Tex. It will serve 10 counties in West Texas, as well as bordering counties in New Mexico and Arizona and the adjacent state of Chihuahua, Mexico. A group of citizens will serve as trustees of the Providence Memorial Hospital, a 2 million dollar general hospital and nurse training school and residence. It is expected that these facilities will raise the ratio of hospital beds in the area from 2.08 to 4.5 per thousand.

WEST VIRGINIA STRENGTHENS PERMISSIVE HEALTH UNIT

LAW

The West Virginia legislature, on February 6, passed House Bill 52 permitting cities and counties to merge

their health departments into one city-county unit serving the entire county. The state's earlier permissive legislation made no provision for consolidation of already existing full-time county and city health departments but gave a full-time county department jurisdiction over its contained municipalities with part-time health officers.

SUMMARY OF MILK-BORNE DISEASE OUTBREAKS—1923–1945

The Milk and Food Section of the Sanitary Engineering Division, U. S. Public Health Service, has prepared a Summary of Milk-borne Disease Outbreaks Reported by State and Local Health Authorities as Having Occurred in the United States During the Years 1923–1945; inclusive.

Included in the summary are figures on the number of outbreaks, cases, and deaths for typhoid, paratyphoid, scarlet fever and septic sore throat, diphtheria, dysentery, food poisoning and gastroenteritis, undulant fever and miscellaneous.

INDIANA LEGISLATURE INCREASES HEALTH APPROPRIATIONS

The 1947 Session of the Indiana State Legislature appropriated for the State Health Department \$750,000 and \$780,000 respectively for the two years of the biennium. This is double the appropriation for the year 1946. In addition the Legislature appropriated nearly two million dollars for a new state public health building, to be a unit of the University of Indiana Medical Center at Indianapolis.

The Legislature also passed laws authorizing county, city-county or multiple county health units. The present five state districts were also legalized, as was the Industrial Hygiene Division heretofore operating under an executive order. A bill to provide state financial assistance to local governmental units for the establishment and maintenance of full

time health departments was defeated however. It had the support of farm organizations and the state PTA Congress and will be reintroduced at the 1949 Session of the Indiana Legislature.

DR. MARTHA M. ELIOT TO SERVE INTERNATIONAL CHILDREN'S EMERGENCY FUND

It was announced on April 20 at United Nations headquarters, New York, that a survey of the relief programs now being carried out in several Central and Eastern European countries will be undertaken by the International Children's Emergency Fund, an agency of the United Nations. Dr. Martha M. Eliot, Associate Chief of the U. S. Children's Bureau, Washington, and President-Elect of the American Public Health Association, is now on leave from the Bureau as Chief Medical Consultant for the Fund.

It is expected that a group of four health and medical officers will spend several weeks touring children's institutions and inspecting other facilities. The survey will be under the direction of Dr. Ludwig Rajchman, Chairman of the Board which operates the Emergency Fund. It is expected that the Fund will help feed 20 million children, carrying out its own work through the national relief services which have been set up in each country.

NEW YORK ACADEMY MEDAL TO DR. MILLER

At its recent convocation meeting marking the end of the Centenary Celebration, the New York Academy of Medicine's Medal Award was presented to James Alexander Miller, M.D. In this citation, George Baehr, M.D., President of the Academy, referred to Dr. Miller's long activity in tuberculosis prevention, as an associate of Dr. Bigg's and Dr. Park, as president of the New York and the National Tuberculosis Associations, and as member of the

Committee on Public Health Relations for all of its 35 years, during 13 of them as Chairman.

At the convocation ceremonies also 21 distinguished physicians from various parts of the world were elected to honorary fellowship in the Academy. Two are Americans, Ernest William Goodpasture, M.D., Dean of the Vanderbilt University School of Medicine, and Alfred Newton Richards, M.D., Vice-Provost in charge of medical affairs of the University of Pennsylvania. The other 19 were: five from Great Britain, two from Sweden, and one each from Argentina, Belgium, Canada, Denmark, France, Germany, Great Britain, Holland, Ireland, Yugoslavia, Mexico, and Russia.

Among these are Sir William Wilson Jameson, Chief Medical Officer of the British Ministry of Health; Dr. Thorvald Madsen, former President of the Health Committee of the League of Nations; Dr. Manuel Martinez-Báez, Professor of the Medical School of the Nacional University of Mexico; Sir John Boyd Orr, Director-General of the United Nations Food and Agricultural Organization; Professor John Alfred Ryle, Head of the Institute of Social Medicine, Oxford University; Dr. René Sand, Professor of Social Medicine, University of Brussels; Dr. Henry Ernest Sigerist, former Director of The Johns Hopkins University Institute of Medicine and now in Switzerland continuing his studies in the history of medicine, and Dr. Andrija Stampar, Chairman of the Interim Commission of the World Health Organization.

Also elected to membership were 17 Corresponding Fellows from 10 countries. Included in this number Sir Alexander Fleming and Sir Howard Walter Florey, cowinners of the Nobel Prize for their work on penicillin, Dr. James MacAlister Mackintosh, Dean of the London School of Hygiene, Dr. Francisco deP. Miranda, Director of the Na-

tional Institute of Nutrition in the Mexican Ministry of Public Health and Assistance; and Dr. Jacques Victor Jules Parisot, Director of the Regional Institute of Hygiene at Nancy.

A number of awards were made at this meeting also; ten Bowen-Brooks scholarships of \$500 each given to young men returning from service for continued medical study. One Louis Livingston Seaman award of \$1,000 and three of \$500 each for aid in investigation in bacteriology or sanitary science were given respectively to James M. Neill, M.D., Cornell University Medical College, Arnold W. Pratt, M.D. of the same university, A. M. Poppenheimer, New York University College of Medicine and Samuel Prigal, M.D. The Edward N. Gibbs Memorial Prize of \$1,500 was awarded to Stanley E. Bradley, M.D., College of Physicians and Surgeons.

PROFESSOR IRVING FISHER OF YALE DIES

Irving Fisher, Ph.D., Professor Emeritus of Political Economy at Yale University and internationally known economist, died in New York on April 29 at the age of 80. Dr. Fisher joined the American Public Health Association in 1903, receiving the 40 year membership certificate in 1943. He was a Fellow of the Vital Statistics Section and a Life Member. He was well known for a sustained interest in the economic value of life and in life extension. In late years he gave untiring efforts to plans for the prevention of inflation, having appeared in Washington on this subject in February just preceding his 80th birthday.

PERSONALS

Central States

A. C. CURTIS, M.D.,[†] Director of the Division of Tuberculosis Control of the Arkansas State Health Department has resumed his duties after a

year's leave of absence during which time he has secured the Degree of Master of Public Health, in the Columbia University School of Public Health, New York, N. Y.

THOMAS D. FITZGERALD, M.D., M.S.P.H.,† formerly Physician in Health Service and Lecturer in Hygiene, University of Michigan, Ann Arbor, Mich., has been appointed Director of Health Service, Illinois State Normal University, Normal, Ill.

CHANGES IN ILLINOIS HEALTH OFFICERS:

L. L. VITT, M.D., has been appointed to the position of Health Officer of the Fulton County Health Department effective April 1.

DALE SCHOLZ, M.D.,† formerly Health Officer of the City of Middletown, Conn., has been appointed Health Officer of the Lawrence-Wabash County Health Department, effective June 1.

GEORGE H. AGATE, M.D., has been appointed as Health Officer of the Will County Health Department, Joliet, effective May 1, succeeding CECIL A. Z. SHARP, M.D.,* who resigned effective April 1. Dr. Agate was formerly employed as Director of Maternal and Child Health Program in the Peoria, Ill., City Health Department.

STEWART C. THOMSON, M.D.,† has been appointed Assistant Professor, School of Public Health, University of Minnesota, Minneapolis, Minn. During the War Dr. Thomson was with the Office of the Surgeon General, Washington, D. C., as Chief of the Collection Branch and as liaison officer with G-2, W.D.G.S.

Eastern States

MATTIE J. BULLARD, M.D.,† formerly Major, UNRRA, New York, N. Y., has been appointed Director, Medical Department, Indiana Public Schools, Gary, Ind.

CLYDE K. CONRAD, M.D., has been appointed Deputy Administrator of Health Services of the North Atlantic Area of the American Red Cross. Dr. Conrad was associated with the Brewster Aeronautical Corporation as Medical Director before the war. During the war he was Flight Surgeon with the 12th Air Force and Base Surgeon of the Glider Base in Italy.

MATILDA E. DYKSTRA, formerly with the New York City branch of the Veterans Administration, where she was chief of the nursing division, has been transferred to the National Branch in Washington, D. C., as Deputy Director of the Nursing Service.

HERBERT R. EDWARDS, M.D.,† Director of the New York City Department of Health, Bureau of Tuberculosis, has been appointed to succeed FRANK KIERNAN* as Executive Director of the New York Tuberculosis and Health Association upon the latter's retirement on September 1, 1947. Dr. Edwards is Assistant Professor of Public Health and Preventive Medicine at Cornell Medical School, Lecturer in Public Health Practice at Columbia University, Advisory Consultant to the Tuberculosis Control Division, U. S. Public Health Service.

CARL L. ERHARDT† has resigned as Assistant Registrar of Records of the New York City Department of Health to accept a position as Assistant Director of Vital Statistics of the State Health Department of Connecticut, State Office Building, Hartford.

GEORGE FAULKNER, JR., D.M.D., has joined the staff of Maine's Bureau of Health to operate the Bureau's Mobile Dental Unit serving areas where dental service is not otherwise available.

WILLIAM M. HAENZEL† became director of the Bureau of Vital Statistics, Connecticut State Department

of Health, on April 1. He succeeds WILLIAM C. WELLING who died last August. Mr. Haenzel had been associated with the New York State Department of Health since 1934.

ERNEST E. HUBER, M.D., has been appointed Senior Surgeon, Regular Corps, Active Duty, U. S. Public Health Service, New York, N. Y. Dr. Huber served until recently as Senior Surgeon, U.S.P.H.S. First Service Command, Boston, Mass.

RICHARD JONES, M.D., has resigned as Assistant Director of Health and Director of the Division of Venereal Disease Control in Maine, to reënter private practice. He will continue to direct venereal disease control work on a part-time basis.

DORIS LONGMAN and HARRIET STEVENS have been appointed to the staff of the Nutrition Service of the New York State Department of Health. Miss Longman has had nutrition teaching experience as well as field work with the Michigan and North Carolina State Health Departments; Miss Stevens recently completed five years with the Army Medical Corps as hospital dietitian.

DENNYS L. LYALL, PH.D.,* formerly Assistant Director in Charge of Antitoxin, Serum, and Vaccine Laboratories, New York State Department of Health in Albany, recently accepted the position of Health Inspector with the City Health Department of Salisbury Municipality, Southern Rhodesia, Africa.

SIBYL MANDELL, M.D., was recently appointed chief of the newly established Division of Mental Hygiene in the Bureau of Child Hygiene of Baltimore City Health Department. Dr. Mandell was most recently on the staff of the Bureau of Maternal and

Child Health of the New Jersey State Health Department.

ROSCOE L. MITCHELL, M.D.,† retired on April 30 as Director of the Bureau of Health of the Maine State Department of Health and Welfare. He has reëntered private practice which he left to join the State staff in 1930. He has been succeeded by DEAN FISHER, M.D., one of the state's district health officers, who was also a state district engineer before he studied medicine.

M. VIRGINIA PARSONS, R.N.,† formerly with the Program Development, National Tuberculosis Association, New York, N. Y., has been appointed Executive Secretary of the New Haven, Conn., Tuberculosis and Health Association.

ALEX J. STEIGMAN, M.D.,† will resign from the Department of Pediatrics of Temple University Medical School, Philadelphia, Pa., to serve as Senior Fellow in Pediatrics of the National Research Council. He will work at the Children's Hospital Research Foundation, Cincinnati, Ohio, under ALBERT B. SABIN, M.D., commencing June 1, 1947.

LEON S. STONE, PH.D., Bronson professor of comparative anatomy, Yale University School of Medicine, New Haven, Conn., will receive the Robert W. Doyne Memorial Medal, an annual award of the Oxford Ophthalmological Congress in England. Dr. Stone who will go to England next summer to address the congress at Keble College, Oxford, was given the award in recognition of his work on retinal regeneration and vision experiments in transplanted eyes.

Southern States

ARTHUR G. BAKER, M.D.,† formerly Director, Johnson-Magoffin County Health Department, Paintsville, Ky., has been appointed Director, Allegan County Health Dept., Allegan, Mich.

* Fellow, A.P.H.A.
† Member, A.P.H.A.

JAMES R. COPELAND,† formerly Bacteriologist in Charge, Elkton Branch Laboratory, Maryland State Department of Health, has been appointed Bacteriologist in the Veterans Administration, Legion, Tex.

GLENN J. HAWKINS† until recently Sanitary Technician with the Army Air Forces has been appointed Public Health Engineer, Sanitary Engineering Division, State Department of Public Health, Richmond, Va.

MARGUERITE L. HAYS, R.N.,† formerly Director, Health Council, Council of Social Agencies, Dallas, Tex., has been appointed Executive Secretary of the newly organized Dallas Health Museum.

RALPH H. HEEREN, M.D.,* has been appointed head of the epidemiology section of the Oklahoma State Health Department. He has been director of the Hutchinson Memorial Clinic, Tulane University School of Medicine, New Orleans, La.

N. V. HENDRICKS, JR., has been appointed Industrial Hygienist on the executive staff of the Standard Oil Company of New Jersey beginning April 15. Just before accepting this position he was unanimously elected the first honorary life member of the Georgia Society of Professional Engineers. He has been in the Division of Industrial Hygiene of the Georgia Department of Public Health, most recently as Assistant Director.

JOE G. HUFSTEDLER, M.D., M.P.H.,† formerly Director, Knox County Health Unit, Tenn., has been appointed Resident in Pediatrics, Methodist Hospital, Memphis, Tenn.

JOHN M. McDONALD, M.D., D.P.H.,* has been appointed Director of the Division of Industrial Hygiene, Florida State Board of Health, beginning February 1. For the past ten years

Dr. McDonald was Director of the Bureau of Occupational Diseases in the Baltimore, Md. City Health Department.

DONALD B. McMULLEN, M.D.,† associate professor of Preventive Medicine and Public Health, University of Oklahoma School of Medicine, has been granted a 2 year leave of absence to become Senior Parasitologist with the 406th Medical General Laboratory, U.S.A., in Tokyo. During the War Dr. McMullen was a member of the Commission on Schistosomiasis, Army Epidemiological Board, receiving a Medal of Freedom for his work in the Philippines and Japan.

GEORGE A. NEVITT, D.D.S., M.S.P.H.,* formerly Dental Consultant to UNRRA in Washington, D. C., has been appointed Senior Dental Surgeon, U.S.P.H.S., District 2 with headquarters in Richmond 19, Va.

RUSSELL C. NYE, M.B.A.,† formerly Administrator Parkland Hospital, Dallas, Tex., has been appointed Executive Administrator, Northwestern Hospital, Minneapolis, Minn.

Western States

CAROLYN DITTON, formerly Orthopedic Advisory Nurse with the Washington State Health Department, has been appointed Head Orthopedic Nurse at the Mt. Edgecumbe Orthopedic Hospital at Sitka, Alaska. It is the only orthopedic hospital in Alaska and is a coöperative project of the Territorial Department of Health and the Alaska Native Service.

HORACE J. DODGE, M.D., M.P.H.,† formerly Director of the Kootenai County Health Unit, Idaho, has been appointed Assistant Professor of Public Health, University of Colorado School of Medicine, Denver, Colo.

HAROLD M. ERICKSON, M.D.,* Oregon State Health Officer, has been appointed Assistant Professor of Public Health and Preventive Medicine, The

* Fellow, A.P.H.A.

† Member, A.P.H.A.

University of Oregon Medical School. He will give occasional lectures at the Medical School in Portland, Ore.

JEANNETTE (SNYDER) HILLER, R.N.,† who served until recently with the UNRRA Mission in Greece is now Divisional Supervising Nurse in the Production and Marketing Division, Labor Branch of the U. S. Department of Agriculture with headquarters in Portland, Ore.

FRED R. INGRAM, M.S.,* has been appointed Senior Industrial Hygiene Engineer, Bureau of Adult Health, State Department of Public Health, Berkeley, Calif. Mr. Ingram was formerly Chief, Division of Industrial Hygiene, University of Colorado, Denver, Colo.

HARRY S. STAHR, M.D.,† has been appointed Assistant Surgeon, Captain of the Veterans Home of California, Napa County, Calif. Dr. Stahr was formerly School Physician, Los Angeles Public Schools, Calif.

MAURICE D. VEST, M.D.,† has been appointed as Director, Maternal and Child Health Section, Oregon State Board of Health. He was formerly Director of the Division of Crippled Children in the Colorado State Health Department.

ALFRED T. WILLIAMS, C.P.H.M.,† most recently Assistant Sanitation Officer and Rodent Control Officer of the U. S. Naval Operating Base in the Midway Islands, has been appointed Chief Sanitary Inspector, U. S. Naval Station, Division of Sanitation, San Diego, Calif.

Foreign

ARTHUR STOLL, M.D., Basle, Switzerland, internationally known authority in pharmaceutical chemistry, has been honored with the publication of a special anniversary issue of the *Swiss Medical Journal*.

Deaths

RAY G. HULBURT, Editor of the *Journal of the American Osteopathic Association*, died on April 15 after a 4 months' illness.

WILLIAM M. MCKAY, M.D.,† State Health Commissioner of the Utah State Department of Health, Salt Lake City, died April 13. Dr. McKay had served for several years, during which time the department had been greatly strengthened. He cooperated in the building of the Utah Public Health Association into a state professional society of vigor and influence.

DWIGHT M. WARNER, Lecturer in Social Hygiene for the Wisconsin State Board of Health, died March 24 in an automobile accident.

*Bureau of Laboratories, Michigan Department of Health, Western Michigan
Division, Grand Rapids, Mich.*

IN early 1943, in connection with an investigation of the antigenicity of pertussis vaccines, particularly as measured by animal protection, a coöperative study was undertaken with a group of interested manufacturing laboratories. As a starting point, samples of vaccine were submitted for comparative density determinations. The findings indicated that a photometric method was reasonably reliable and reproducible, under properly controlled conditions. For example, the calibration chart for each particular instrument should be based on a series of graded dilutions of a suspension of organisms having the size and morphology of smooth *Hemophilus pertussis*; the suspension must be of known density based on a series of di-

rect counts; and it should be practically free from color and extraneous matter. An unknown suspension to be standardized as to density also must meet certain requirements. It is clear that a suspension in which the organisms are large and pleomorphic, or one highly colored or containing extraneous matter could not be read correctly in terms of the calibration chart. With these conditions in mind, in the comparative protection tests which were planned, we chose the photometric procedure for measuring the bacterial suspension for the immunizing and challenging doses.

Preliminary experience with pertussis mouse protection tests, using the intracerebral route for challenge was reported to the Subcommittee on the Evaluation of Administrative Practices,¹ and discussed at the Biologic Section of the American Drug Manufacturers Association in October, 1944. As stated in that report, the need for a test of the potency of pertussis vaccine had long been recognized. During sev-

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946.

Sponsored by the Subcommittee on the Evaluation of Administrative Practices of the A.P.H.A., with the aid of funds granted by laboratories in the Biologic Section of the American Drug Manufacturers Association.

eral years in experiments with approximately 12,000 mice we had accumulated data on protection tests in which the mice were infected with mucin-suspended organisms by the intraabdominal route. Protection could be demonstrated by that method and the results were sufficiently encouraging to stimulate investigation. Such a procedure has been used with some success by other workers, notably Holm and Bunney.² However, after many trials of various combinations of dosage, interval, and challenge, we were unable to standardize the procedure with reference to a satisfactory potency test. The question of route of infection was therefore given further consideration.

Based on relatively limited trial it appeared that the intranasal method of infection, although suitable for certain investigative work, did not answer the need for a potency test. The experience of Norton and Dingle³ with the intracerebral route of infection in mouse protection tests in typhoid led us to try that route in pertussis. Norton⁴ also reported to us his results in some preliminary pertussis protection tests, which stimulated us to investigate this method further. Concurrently, work along similar lines has been in progress at the National Institute of Health, under the direction of Margaret Pittman.⁵

In the first comparative tests,¹ varying degrees of protection were demonstrated with twelve different samples of vaccine submitted by the coöperating laboratories. The results were so encouraging that plans were immediately outlined for study of the factors involved in the development of a practical test, and for carrying out at the earliest possible date some comparative tests among the interested laboratories. These tests performed by different workers in their own laboratories would test the reproducibility of results and point the way to improvements in technique.

METHODS

Each laboratory was to test a reference antigen in comparison with an antigen of its own choice, according to a common procedure as outlined. Materials were furnished as follows: (a) mimeographed outline of procedure; (b) a challenge culture of *H. pertussis*, No. 18-323, which had been found to have an LD/50 in the range 200 to 500; and the challenge dose specified to be 40,000; (c) a reference antigen prepared from single culture 10-536 L₁, to be used for checking the photometric standardization of dosage in the different laboratories, as well as for immunization of mice in the tests; and (d) forms and sample protocol, with the method of Reed and Muench⁶ specified for determining the 50 per cent end points of the lethal and immunizing doses.

Course of disease in intracerebrally infected non-immunized mice—Intracerebral infection of mice with *H. pertussis* has proved particularly suitable for use in protection tests because of the clear-cut incubation period, and the orderly progress of symptoms in a typical clinical syndrome which ends in death. Following intracerebral injection under anesthesia with an infective dose of *H. pertussis*, the non-immunized mouse shows a series of typical symptoms. After recovery from the anesthetic, the mouse usually appears normal for a number of days. This incubation period varies with the animal and with the dose. For example, following a dose of 20,000 organisms of a highly virulent culture, it is usually 4 to 5 days before the first symptoms of illness; with a larger dose the symptoms may appear earlier, and with a smaller dose, later. Most deaths occur within 2 weeks after infection.

At first the mouse becomes inactive and the coat appears ruffled. The animal is irritable and sits in a hunched position, with the head lowered and appearing to be bulged. Following these

first indications of illness, there is a progressive loss of muscular control, and avoidance of food. During the next 48 hours, the mouse becomes prostrated and shows convulsive motions, breathing becomes labored and death usually follows after a few hours. Death seldom occurs without these typical signs of encephalitis. *H. pertussis* can be isolated from the brain, and multiplication of the organisms in the brain is easily demonstrated. Histological examination reveals brain abscess and encephalitis. There is infiltration of the choroid plexus and ependyma with wandering and polymorphonuclear cells.*

Certain technical factors in the development of a procedure—Selection of a challenge culture with a small killing dose was of prime importance. From preliminary experiments with the intracerebral route of infection it was observed that smooth cultures of *H. pertussis* varied greatly in lethal dose. Cultures which had similar growth characteristics and agglutinability, and which gave comparable protection in mice when used as immunizing antigens, were found to vary in LD/50 from 200 organisms to several million. Fortunately, culture No. 18-323, one of the most virulent yet found, was among the first to be tested, and it was chosen for use in the comparative tests. Storage in the dried state has been found to maintain the culture's virulence, according to our present experience.

In the first experiments salt solution was used for suspending the organisms for brain inoculation, but viability tests by means of colony counts showed that the pertussis bacilli died so rapidly that the first and last mice injected in an experiment received very different numbers of living organisms. Cultures suspended in a 1 per cent solution of Casa-

mino acids (Technical Difco) in distilled water, were found to remain viable for several hours, a period more than satisfying the conditions of the test. The Casamino acid solution was considered especially satisfactory because it was easily reproducible and it was accepted for routine use pending further study.

Standardization of the suspension for the challenge dose was recognized as a prerequisite to reproducibility of results. In order to obtain consistent LD/50 results in different experiments the utmost care must be used in controlling those factors which are known to influence the results. For example, uniform conditions of the challenge culture should be maintained, including medium, incubation time, and temperature; there should be careful standardization of the photometer; precise technique in dilution of the suspension, such as the use of a separate pipette for each dilution; and the diluted suspension should be injected into the mice within a short time after preparation to insure viability.

The question of immunization dosage in relation to challenge required considerable preliminary work. In the first tests, a constant immunizing dose and graded challenge doses were tried, but frequently sharp end points were not obtained. In experiments in which the challenge dose varied from 100 to 10,000 times the LD/50 it was found that in the higher ranges even a 10-fold increase had little effect on the end point. A graded immunization schedule with a constant challenge dose proved far more sensitive, and in the proper range resulted in reproducible end points.

Condensed outline of procedure chosen for the comparative test—

Mice—White Swiss mice, 12 to 14 gm., all one sex or sexes equally distributed, were caged in groups of 15 each. Three groups were used for each

10-1	470	80	0.21	0.12	1.8
10-2	80	500	0.45	0.40	1.1

- Notes: 1. The LD/50 (number of organisms) is rounded to nearest 10.
 2. Figures for ImD/50 (in billions) are rounded to two decimal places, for purposes of comparison.
 3. Test vaccine refers to the one selected by each laboratory.
 4. Laboratory 6: The test antigen (a) was the same antigen in experiments A and B.
 5. Laboratory 9: The three test antigens in the three tests A, B, and C bore different numbers.
 6. Laboratory 10: The culture suspensions were standardized differently in the two tests.
 7. Definitions: LD/50 is the number of organisms which kills 50 per cent of a group of mice; ImD/50 is the total immunizing dose (in billions) which protects 50 per cent of a group of mice against the challenge culture dose; 50 per cent endpoints computed by Reed Muench method.

antigen tested and four groups for controls.

Immunization—From a stock suspension of 10 billion per ml. based on photometer readings, dilutions were made in saline as required. The total doses for the 3 groups of mice for each antigen were respectively, 0.08 bil., 0.4 bil. and 2.0 bil., each total amount divided in two 0.2 ml. doses injected intraabdominally, with a 5 day interval between injections. Injected mice and controls were allowed to rest for 10 days. (We are now using a single injection, and a graded dosage schedule designed to bring the ImD/50 relatively close to the middle of the three doses, such as 0.06, 0.3, and 1.5 bil.)

Preparation of challenge suspension—The dried culture No. 18-323 was revived on Bordet-Gengou medium, a second subculture grown for 48 hours and subculture No. 3, 4, 5, or 6 used for injection after a 24 to 30 hr. incubation period. The growth was harvested into a 1 per cent solution of Casamino acids (Technical Difco), adjusted to pH 7.0-7.2; checked for purity and morphology by Gram stain; and standardized to 5 bil./ml. based on photometer readings. Dilutions were made in Casamino acid solution for injection of the challenge culture in doses of 80, 400, 2,000, and 40,000 organisms, respectively, each dose in 0.04 ml. volume for the mice in the control groups; and 40,000 for all the immunized mice. Viability of the organisms was checked by colony counts, which are usually from one-fourth to one-half the number of organisms indicated by photometer readings.

Intracerebral injection — The mice were injected under anesthesia (2 parts ether and 1 part chloroform) within 2 hours of dilution of the culture suspension. A $\frac{1}{4}$ ml. syringe with $\frac{3}{8}$ in. 27 gauge needle was used and the needle inserted slightly to one-side of the midline and just in front of the "hump."

Observation period—The mice were observed daily for 14 days and the number of deaths was recorded. (In the summary at the end of the 14th day, prostrated mice may be included as deaths.)

RESULTS OF COMPARATIVE TESTS

The form in which the results were submitted is illustrated in the protocol for Laboratory No. 7, Grand Rapids (see Table 1).

From similar protocols submitted by all the laboratories, a summary of end points has been made in Table 2.

The LD/50 results obtained by the ten laboratories—Considerable difficulty could be anticipated in reproducing the LD/50 of the challenge culture in different laboratories. The virulence could vary according to growth conditions because of unknown factors; there could be variation in the number of organisms injected due to technical factors related to standardization and preparation of the challenge suspension; there is possibility of variation in mouse strains; and technical factors related to injections into the mouse brain, such as variation in the injection site or loss of part of the inoculum by oozing after use of a needle with a rough point, could influence the result.

Actually the consistency of the LD/50 results is most encouraging. If the LD/50 end points in the summary are arranged in order, it is found that the middle half are between 200 and 480; 10 of the 14 lie between 160 and 480, with a mean of 310 and a median of 360. While this is gratifying, it is very important that every effort be made to explain the extreme results. It should be mentioned that two laboratories that did not submit protocols for inclusion in the summary, reported later that they had obtained unsatisfactory LD/50 results.

As shown in the summary of end points in Table 2, the challenge dose of

TABLE 3
Expression of LD/50 and Challenge Dose by Photometer Density

Lab. No.	Plate Count		Ratio: Column 1 to Column 2	LD/50		Challenge Dose		Ratio: Challenge Dose to LD/50
	Number of Organisms Planted (Photometer) (1)	Number of Colonies (2)		By Photometer	By Colony Count	By Photometer	By Colony Count	
1	None	320	...	40,000	120
2	400	101	4.0	480	120	40,000	10,000	80
3	400	158	2.5	360	140	40,000	16,000	110
4	None	400	...	40,000	100
5	400	67	6.0	1,870	310	40,000	6,660	20
6A	160	150	1.1	250	230	40,000	36,360	160
6B	160	65	2.5	220	90	40,000	16,000	180
7	400	148	2.7	160	60	40,000	15,000	250
8	400	161	2.5	200	80	20,000	8,000	100
9A	400	95	4.2	600	140	40,000	9,520	70
9B	400	100	4.0	730	180	40,000	10,000	50
9C	None	170	...	40,000	230
10-1	400	76	5.3	470	85	40,000	7,550	90
10-2	None	80	...	40,000	500

Note: For the sake of comparison, the colony counts are tabulated for a plate inoculum of 400 organisms by photometer readings; if the 400 inoculum was not used by a particular laboratory the next lower figure was selected.

40,000 as used by the ten laboratories varied from 20 to 500 times the LD/50, but the majority were in the range 100 to 250. Since the dose was determined on the basis of density, the question arose as to the viability of the organisms injected. In Table 3 the LD/50 and challenge dose in ten tests are given, based upon photometer readings and also upon colony counts.

In the majority of these tests, the ratio of the number of organisms planted (based on photometer) to number of colonies varied from 2.5 to 4.2. With regard to the colony counts it should be remembered that *H. pertussis* frequently occurs in pairs, so that colonies could be expected to be fewer than the actual number of organisms. Clumping would also result in fewer colonies. Poor growth conditions for single colonies (for instance medium containing peptone) might account for further reduction in the number of colonies. Referring to the table, it is evident that whether LD/50 and challenge doses are expressed in terms of photometer or colony counts, the ratio remains the same. In expressing the results of the

test it is probably simpler to use the photometric density, using colony counts only as a consistency check.

ImD/50 results with the reference vaccine—It is obvious, from the indeterminate end points of the reference vaccine in six of the tests, that the vaccine dosage schedule as chosen was in too high a range for this antigen. With a properly balanced test the 50 per cent end point should be fairly close to the middle of the dosage range. Based on inspection of the results, the ImD/50 of the reference vaccine, under conditions of the test, is of the order 0.1 billion. The similarity of the results obtained by most of the laboratories was gratifying. The one end point farthest out of line was 1.03 billion, obtained by laboratory 6 A. This laboratory subsequently accounted for the high result on the basis of the particular mouse strain used.

ImD/50 results with the various test vaccines—Of the 17 test vaccines only one gave an ImD/50 value less than the reference vaccine. However, several gave results which were very close and only a few had end points which could

be considered significantly higher. In the interpretation of the end points obtained with these test vaccines, it is recognized that more experience is required before the significant limits of variation can be determined or the results defined in terms of potency.

The need for an antigen of reference is emphasized by the results of the comparative tests, as listed in Table 2. For example, test vaccine No. 1 has an ImD/50 value considerably less than vaccine 6 B(b). However, vaccine 1 has an ImD/50 value approximately three times that of the reference antigen, while vaccine 6 B(b) has a value which is nearly the same as that of the reference vaccine. The evaluation of an antigen in relation to a standard of known strength would appear to be more reliable than the actual ImD/50, since the latter does not allow for the technical variations which are bound to occur in different experiments. Also, a reference vaccine would avoid false conclusions in the instance of the use of a strain of mice that required a smaller or larger immunizing dose than the mice ordinarily used.

Analysis of results—While the Reed Muench method was used for calculating the 50 per cent end points, the data have been examined also by the method of Bliss⁸ modified by Litchfield and Fertig.⁹ The results would not add materially to the present report but they do lend support to the validity of the test.

GENERAL COMMENTS

In much of the discussion during the years on problems of pertussis vaccines, a base line for comparison has been lacking. While tests for agglutinins, opsonins, and complement-fixing antibodies have been used for what information they would give, workers have felt the need of a suitable animal protection test. Results of the comparative series presented here suggest that the intra-

cerebral mouse test offers promise as the basis for a potency test by which the antigenicity of pertussis vaccine can be judged. A tentative outline on similar lines was sent recently by the National Institute of Health to manufacturing laboratories in connection with the development of minimum requirements for pertussis vaccines.⁵ Another application is the study of different methods of preparing vaccine, illustrated by the recent paper by Cohen and Wheeler⁷ on pertussis vaccine prepared in fluid medium. Also when the technical details have been worked out for applying the procedure to passive tests, a tool may be available for studying such a fundamental problem as pertussis vaccine dosage in terms of the mouse protective properties of the serum of immunized children; and for evaluating therapeutic antisera. Perhaps most important of all is the use of the test in the selection of highly antigenic cultures for vaccine production.

In connection with the choice of a particular technical procedure for the intracerebral mouse test, further work and more experience are required. It needs to be remembered that there may be considerable variation in technique depending on the purpose of the test. For example, in a potency test which is to be the basis for acceptance or rejection of a vaccine, a dosage range for immunization will be chosen which is suitable for the vaccine of reference. If, on the other hand, there is to be a quantitative comparison of antigens, there may need to be a preliminary test to find the range. In passive tests with serum of relatively low antibody content, it is probable that care must be taken to use a relatively smaller challenge dose than the large ones that can be used in active tests.

SUMMARY

Mouse protection tests, using the intracerebral route for challenge, were

used in a series of comparative tests by ten laboratories.

The comparative results with the procedure as outlined demonstrated a good degree of reproducibility in the hands of different workers, and the method detected differences in vaccines in relation to a reference antigen.

Certain technical factors are discussed, particularly the interrelationship of the different parts of the procedure and the need for a reference antigen.

A mouse protection test such as used in this study is suitable as the basis for a pertussis vaccine potency test; it is applicable to the choice of cultures for vaccine production; and it is a promising method for investigation of fundamental problems in pertussis.

ACKNOWLEDGMENT: The authors are grateful to E. S. Weiss, Tuberculosis Control Division, U. S. Public Health Service, for his statistical treatment of the data; they acknowledge their good fortune in the interest of J. Ipsen, Chief of Biological Stand-

ards, State Serum Institute, Copenhagen, who studied the data and carried out certain statistical analyses; and thanks are due L. Portwood, Biological Products Division, Michigan Department of Health, for preparation of the reference antigen.

American Museum of Health

The American Museum of Health is working on plans for the revitalization of the Museum, where they were temporarily terminated at the beginning of World War II.

The Museum is very anxious to obtain several copies of the book *Your Health*, which served as a guide to the exhibit during the second year of the World's Fair in 1940. Its supply of this publication was depleted by water

damage, while in storage. If you have a copy, the Museum would greatly appreciate your mailing it to its Secretary, Homer N. Calver, Room 806, 1790 Broadway, New York, N. Y.

The Museum does have a supply of *Man and His Health*, which served as a guide for 1939. If you are interested they would be very pleased to send you a copy of this book in exchange for your copy of *Your Health*.

Wartime Army Medical Laboratory Activities

The Wartime Army Medical Laboratory Organization *

GUSTAVE J. DAMMIN, M.D.

Assistant Professor of Medicine and Pathology, Washington University School of Medicine; Director of Laboratories, Barnes Hospital, St. Louis, Mo.; Formerly, Director, Laboratories Division, Preventive Medicine Service, Office of the Surgeon General

IT was indeed a pleasure to be invited to give an account of the wartime organization and activities of the Army's Medical Laboratories. Particularly to those who were in a position to observe and be part of the activities in the Surgeon General's Office, the Army Institute of Pathology and the Army Medical School, as well as in laboratories in the Zone of the Interior and overseas, it is a record of achievement that can be related with a sense of pride and accomplishment.

The medical laboratories were supporting a force active under every possible climatic condition. Laboratory units with responsibilities primarily clinical, public health, or research, or a combination of these, were appropriately assigned in the Zone of the Interior or continental United States, and overseas. For a proper appreciation and understanding of the scope of operation of the Army Medical Laboratories it would be necessary for a Medical Department officer to have had a tour of duty in Washington, in one of the Service Commands, and in a Theater of Operations. Let us follow a hypothetical laboratory officer of the Medical or Sanitary Corps through such a series of assignments.

In the Surgeon General's Preventive Medicine Service was the Laboratories Division. This division, in conjunction with other divisions of the Preventive Medicine Service, with Personnel Service, Training Division, Supply Service, and others, with the Army Medical School and the Army Institute of Pathology, was responsible for Army Medical Laboratory policy. Included in its mission were the constant review of technical methods and laboratory equipment, the commissioning, assignment, evaluation, and separation of Medical Department laboratory officers, the review of manuscripts submitted for publication, the formulation of tables of organization and equipment, equipment lists, and the publication of directives, Army regulations, Medical Technical Bulletins, Technical Manuals, Field Manuals, etc., relative to medical laboratory activities.

Our officer would have found the Army Institute of Pathology occupied with rapidly expanding an installation which was (1) providing a world-wide diagnostic service, (2) conducting correlative and analytical studies of problem diseases, such as infectious hepatitis, scrub typhus, trench foot, and coronary artery disease. (3) maintaining a continuous program of officer training in pathology, both resident and by means of teaching collections of slides and clinical data, and (4) providing

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946.

training media through its Illustration Service.

He would have found the Army Medical School concerned with an intensive training program in tropical medicine and special laboratory fields for officers, and a course of laboratory technician training for enlisted men. Diagnostic biologicals, such as Weil-Felix antigens, antigens for serologic tests for syphilis and Shigella and Salmonella typing kits were prepared and shipped to our far-flung laboratories. Definitive studies on submitted cultures, sera, chemical and parasitological specimens, and research on immediate problems were conducted in the various divisions of the school. The Veterinary Division, in addition to training and investigation, was preparing vaccines against equine encephalomyelitis and Japanese B encephalitis.

These installations were conducting clinical, public health, and investigative laboratory studies on a scale never before attempted. The field of neurotropic virus and rickettsial diseases was being intensely studied. The medical officer was being provided a type of diagnostic service never before available through a single agency. This service would unquestionably be a stimulus to broader and better laboratory service in civilian medicine of the future.

Our hypothetical officer would have found active laboratory services in the Zone of the Interior hospital system that was established. There were 65 General, 26 Regional, and 142 Station Hospitals operated by the Army Service Forces alone. Though their work was principally clinical, these laboratories also had opportunity for public health and research laboratory work. Pertinent epidemiological studies of local importance were conducted, newer drugs and laboratory methods were evaluated, methods for determination of drug levels in the blood were devised, and studies of increasingly important problem diseases such as malaria, infectious hepatitis and

schistosomiasis were carried out. A large portion of the technician staff in each hospital laboratory would have been found to be civilians. They formed an important stable staff required by the turnover occurring in enlisted technician staffs to meet overseas needs.

To conserve the small supply of experienced tissue pathologists, 19 histopathologic centers were established. These were usually general hospitals located to serve a number of smaller hospitals in a designated area of a service command. The chief of laboratory service in such a hospital served as a regional consultant. Final review of many specimens was conducted at these centers, thereby leaving only essential material for final disposition at the Army Institute of Pathology.

Facilities in the Z. I. hospitals varied. As the war progressed, the General Hospitals became more concerned with patients returning from overseas. Some became special centers dealing primarily with one or several of the various specialties, tropical diseases, neurosurgery, plastic surgery, etc.

The Regional Hospitals arose from strategically located Station Hospitals and provided general hospital facilities for cases originating in the Zone of the Interior.

The Service Command laboratories, of which there were 10, were designed to supplement the epidemiological, sanitary, and diagnostic laboratory services afforded by other medical department laboratories in the Zone of the Interior. The laboratories were established administratively as part of the Service Command Surgeon's Office, the commanding officer of the laboratory being the Service Command Laboratory consultant, and his staff representing a laboratory consultant staff to the Surgeon. As such, all types of laboratory problems originating within the Command were referred to the Service Command laboratory. On epidemiological prob-

lems the laboratory worked with the Surgeon's preventive medicine officer, on clinical laboratory problems, with the Surgeon's medical consultant. In addition to investigating outbreaks of epidemic diseases such as bacillary dysentery, influenza, and streptococcus infections, the laboratories conducted a continuous evaluation program. This was designed to assist the hospital laboratory officer in evaluating his staff. Known chemical, serological, bacteriological, and parasitological specimens were sent to hospital laboratories for examination. Results of these examinations were reviewed by the Service Command laboratory and the hospital laboratories were rated on a sliding scale. These laboratories also conducted continuous on-the-job training programs for laboratory officers and enlisted technicians.

A large responsibility was delegated to the Veterinary Section of these laboratories. Highly trained technical help and elaborate apparatus were required to examine foods of animal origin purchased for Army consumption. Meats, cheese, eggs, milk, and other dairy products had to meet Army standards of acceptability.

Surveys for insect vectors and definitive identification of such vectors were the work of the entomologist of the laboratory. On such problems, the laboratory worked in coöperation with the Service Command Sanitary Engineer.

The laboratory personnel needs were difficult to meet. Requirements for all types of laboratory specialists were relatively greater in the Army than in civilian life. As need for tissue and clinical pathologists increased, the need for expansion of the Sanitary Corps increased. The Sanitary Corps laboratory officer assumed the important rôle for which he was by training and experience equipped. The Sanitary Corps Reserve had helped considerably in the initial staffing of laboratories, but many more

bacteriologists, chemists, serologists, and parasitologists were needed. Criteria for direct commissioning and commissioning from enlisted status were established. At the height of the war there were over 1,200 Sanitary Corps laboratory officers on duty.

Our hypothetical laboratory officer now has an APO address and writes from a Theater of Operations. The ranking laboratory, the Medical General, provides for the theater the facilities provided by the Army Medical School, the Army Institute of Pathology, and the Service Command Laboratories in the Zone of the Interior. Selected specialists staff this laboratory which represents the Theater Surgeon's consultant staff for the investigation of clinical, public health, and research laboratory problems. The unit consists of 23 officers and 76 enlisted men. The commanding officer is the theater laboratory consultant and as such is in contact with the staff of the Theater Surgeon's Office and the laboratories in the field. The facilities of his laboratory are needed in the study of such immediate problems as infectious hepatitis, shock, influenza, bacillary dysentery, and anaerobic infections. By courier, service is provided other laboratory installations. On technical matters, the laboratory maintains communications with the Office of the Surgeon General, the Army Medical School, and the Army Institute of Pathology.

Special units are delegated to particular problems. Missions whose work involves epidemiological and laboratory investigations are dispatched by the Army Epidemiological Board for the study of diphtheria in Germany and Italy, encephalitis in Okinawa and Japan, schistosomiasis in the Philippines, and other problem diseases overseas, and by the Typhus Commission for the study and control of scrub typhus in the Pacific and Burma, and epidemic typhus in Europe and North Africa.

The material is separable into two categories: those conditions that are incidental and those that are service-connected. From a pathologic standpoint, this latter group is not of so much interest as a public health matter but, of course, it does involve aspects of very great public health importance, especially etiology, epidemiology, and prevention. In the other group there are several features that will be of at least actuarial interest to you, and of considerable importance clinically.

Three groups of these conditions have been selected as illustrative of the possibilities. It is to be remembered that our figures cannot be read as incidences of disease; they are simply the actual number of cases received at the Institute—and the majority are fatalities.

TABLE 1-A

*Representative Incidental Diseases in the
Military Age Group
January, 1940, to June, 1946*

Fatal Coronary Disease.....	945
Fatal Diabetes	75
Aneurysm, Intracranial	180
Periarteritis Nodosa	141
Congenital Single Coronary Artery.....	9
Gynecomastia	435

Any practitioner of experience has seen a case or so of fatal coronary disease in young men, but I do not believe that the comparative frequency of coronary disease in this age group is generally realized. In addition to the fatal cases, we have the opportunity of studying the pathology of the coronaries in the large group that have died as a result of trauma or of disease. The majority of the fatal cases presented no history of previous heart trouble. The Veterans' Administration has begun an extensive follow-up study of those who did have clinical manifestations of cardiac disease and have survived.

The diabetics, likewise, were practically all unsuspected clinically and had been missed on induction examinations.

The item of single coronary artery may seem trivial but one must realize that there are only about twenty cases reported in the literature.

TABLE 1-B

Teratoma, Mediastinum and Lung.....	46
Carcinoma, Bronchus and Lung.....	769
Adenoma, Bronchus	43
Lobectomies for T.B.....	37
Tumors, Bone	559
Tumors, Testis	940

We have been particularly impressed with the high incidence of malignancy, particularly of the lung and, as will be seen in Table 1-C, of tumors of the reticulo-endothelial system and of the blood. The large number of bone tumors and tumors of the testis are not surprising, but the latter group furnish an opportunity for the most comprehensive study of this tumor that has been possible to date. Already it indicates a more precise classification, significant practical prognostic criteria, an appraisal of the effectiveness of various treatments, and some interesting points about embryology, and tumors in general.

TABLE 1-C

Carcinoma, G. I. Tract (Stomach 212).....	553
Carcinoma, Lip	758
Carcinoma, Basal Cell, Skin.....	1,463
Melanoma, Malignant, Skin.....	223
Tumors, Brain	900
Tumors, Reticuloendothelial and Blood.....	2,036
Hodgkin's Disease	568
Giant Follicular Lymphoma.....	124
Leukemias	421

We were particularly surprised at the number of carcinomas of the colon. There is a possibility that environment may be a factor in the high incidence of skin cancer. Much of the training was in our southern states and considerable deliberately in desert environment. Sun, wind, and dust, therefore, have been influences.

An analysis of the brain tumors indicates the necessity for revising our notions of the anatomic and age distribution of various types. The glioblastoma multiforme, for example, was considered a tumor predominantly of

late middle age. The majority of this large group, however, are such tumors and are in those below 40.

We have just about concluded that there is more than the expected incidence of tumors of lymphatic and blood forming tissues. The reticuloendothelial system undoubtedly received a great deal of stimulation as a result of multiple immunologic procedures and there is a possibility that this stimulation became irritation at times.

TABLE 2-A

Service-connected Diseases

Epidemic Hepatitis	
(Subacute)	195
(Acute Fulminant)	141
Lower Nephron Nephrosis	760
Heat Stroke, Fatal	215
Cold Injuries	
(High Altitude, Trench Foot)	500
Injuries of Cervical Spinal Cord	
(Diving Accidents)	140

TABLE 2-B

Guillain-Barré Syndrome, Fatal	48
Infectious Mononucleosis, Fatal	9
Meningitis, Epidemic, Fatal	355
Waterhouse-Fridericksen Syndrome	155
Tuberculosis, Fulminant	681
Rheumatic Fever	125
Myocarditis	1,410

TABLE 2-C

Malaria, Falciparum, Fatal	102
Ruptured Spleens in Vivax Malaria	13
Coccidioidomycosis	98
Scrub Typhus	282
Atabrine Dermatoses	205
Sulpha Drug Fatalities	578

We need not dwell in detail upon the conditions that are service-connected. They are simply presented to indicate the quantity and versatility of our material.

The Army Institute of Pathology began during the Civil War in 1862 as the Army Medical Museum, designed by Surgeon General Hammond to collect material from the battlefields and hospitals that might be used subsequently in the training of Army surgeons. During the years until 1922, the Museum *per se* was the dominant activity. With the enormous impetus of the war, it became obvious, however, that the term "Museum" was inap-

propriate and we were permitted to change the name to the "Army Institute of Pathology."

In addition to the Museum and the Department of Pathology, we have two other divisions that have assumed very important rôles. The Photographic Department, also established during the Civil War, has prospered through the years and branched out more actively during the last war when we organized and equipped nine Medical Arts Units that were sent to the Theaters of Operation. We were also in virtual control of the clinical photography in the general hospitals in this country. From all of these sources, illustrative material poured back to the Institute. In addition to the 90,000 negatives in our original files covering historic subjects and pathology predominantly, we have acquired, therefore, over 100,000 black and white pictures, approximately 30,000 kodachromes and 100,000 feet of motion picture film covering all phases of Medical Department activities and a great deal of clinical photography.

The fourth division is the American Registry of Pathology under the aegis of the National Research Council and made up of fourteen individual registries in various clinical specialties, each in turn sponsored by the parent national society of that specialty. Through these registries we are in very intimate contact with the civilian profession and furnish it consultation service which would not be available so freely otherwise. Included are registries for dental and oral pathology and one of great possibilities, that of comparative pathology sponsored by the American Veterinary Medical Association. In these registries we have accessioned large numbers of cases in the specialized fields. For example, there are over 5,000 bladder tumors; over 20,000 enucleated eyes among which there are about 2,500 melanomas of the uveal tract; over 3,000 lymphatic tissue and

blood tumors, and 850 chest tumors.

This enormous amount of pathologic and illustrative material is available to anyone who is qualified to make legitimate use of it. More specifically, we have developed loan-study sets in various clinical specialties and in more detailed pathologic entities, and have prepared a number of illustrated syllabuses and atlases. These are used particularly by candidates preparing for their special Board examination.

As The Surgeon General became relieved of the urgent and exacting problems of actual warfare, he has had the opportunity to become aware of the possibilities of these great collections

and has energetically been developing plans for the Institute's future. It has long since outgrown its physical facilities, and he proposes to build suitable quarters in a suburban area of Washington to permit not only the exploitation of this accessioned material, but the expansion of postgraduate teaching and research. There will be a research hospital in the Center which will make possible comprehensive studies and training in medico-military problems. The civilian professions will share in this program principally through the Registries by the establishment of fellowships, and by the elaboration of the teaching material.

Passano Foundation Award to Dr. Waksman

Among the events of the American Medical Association's Centennial Meeting in Atlantic City was a dinner on June 12 at which presentation of the 1947 Passano Foundation Award was made to Selman A. Waksman, M.D., microbiologist of the New Jersey Agricultural Experiment Station.

The \$5,000 cash award was presented for Dr. Waksman's original research in the field of antibiotics culminating

in the discovery of streptomycin.

The award was made by Robert S. Gill, President of the Passano Foundation. The dinner was attended by about 100 outstanding medical men. Sir Howard Florey, knighted for his development of the clinical applications of penicillin, made a brief address. Dr. Waksman's address was entitled "Antibiotics and Tuberculosis — a Microbiological Approach."

Wartime Army Medical Laboratory Activities

Public Health Aspects of Wartime Studies Conducted at the
Army Institute of Pathology *

MAJOR RUELL A. SLOAN, M.C., AUS

Executive Officer, Army Institute of Pathology, Washington, D. C.

IN the period between Pearl Harbor and October, 1946, over one hundred scientific papers were completed at the Army Institute of Pathology. In these papers there were many observations of public health significance, and this report is primarily a review thereof. It is also evidence of the friendly relationship and spirit of coöperation which has developed between the pathologists in the field, other branches of the Medical Department, and the Institute. The very existence of the data which allow the preparation of this review is a tribute to medical officers at all levels throughout the Medical Department.

Considering the world-wide distribution of the armed forces during World War II, it is significant that approximately one-half of the six hundred pathologists in the Army served for varying periods at the Army Institute of Pathology, while many others stopped for brief visits. Thus an informal liaison on a professional level was maintained without which the growth and advancement of this center of pathology during World War II would have been greatly curtailed. As a result of the excellent coöperation achieved, medicine in this country has

been provided with an extremely valuable heritage. This heritage must be carefully guarded and its post-war development aided by federal and civilian agencies and the individual members of the medical profession. The full value of the material is not yet evident, but as it becomes so it will be recognized that medicine as a whole is deeply indebted to all pathologists in the Army.

The basic mission of the Institute, namely, the advancement of medical knowledge, is as nonpartisan and non-controversial a project as it is possible to find in this world today, and it deserves the active, unqualified support of every medical scientist.

Colonel Ash has outlined for you the history and development of the Army Institute of Pathology during World War II, including the evolution of its various departments, the plans for its future, and a statistical presentation of the material available for study. It is my privilege as Executive Officer to represent the Wartime Staff of the Institute by a survey of their publications with public health significance.

REVIEW OF SELECTED INSTITUTE PUBLICATIONS

Every war has its outstanding diseases peculiar to the times and circumstances. Malaria and dysentery were widely prevalent during the Civil War, typhoid fever during the Spanish-

* Presented by Major Sloan for the Wartime Staff of the Army Institute of Pathology before the Laboratory Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 14, 1946.

American War, influenza and other respiratory diseases during the First World War, and malaria, scrub typhus, epidemic hepatitis, lower nephron nephrosis, and radiation disease during the war recently ended.

INFECTIOUS DISEASES

In the field of infectious diseases a great many problems arose. Of the bacterial group, cutaneous diphtheria and bacillary dysentery were serious problems in the Mediterranean Theater. Of the rickettsial group, scrub typhus was important in the Southwest Pacific; of the protozoal group, malaria, assumed proportions which required control to avert military failure in several theaters of war. Of the virus group, epidemic or virus hepatitis was of particular significance as the only pandemic disease of World War II. Of the fungus group, coccidioidomycosis was a problem throughout the southwestern training areas of this country. Material of many other diseases has been reported and, through the chain of evacuation set up by AR 40-410,¹ and TB MED 19,² all autopsy and selected surgical material has been forwarded to the Army Institute of Pathology for review and final disposition.

Scrub typhus and other rickettsial diseases are discussed by Major Arthur C. Allen, M.C., and Dr. Sophie Spitz, contract surgeon,³ in a detailed comparative study of the pathology of scrub typhus and other rickettsial diseases. Acute interstitial myocarditis is reported by the authors in 93 per cent of the scrub typhus cases, 83 per cent of epidemic typhus, and 78 per cent of the cases of Rocky Mountain spotted fever. However, a later study⁴ shows no residual changes in the heart in 3 cases in which death from accidental causes followed recovery from scrub typhus. A more complete study of this problem of potential economic value to taxpayers and veterans will require the

coöperation of civilian medicine and the federal services. Actually, an autopsy should be performed in every case of accidental death of a veteran of World War II to determine the residual effects of diseases which prior to the war were unusual in the United States.

Malaria—In a report on the pathology of falciparum malaria,⁴ Dr. Spitz refers to Helsen's report⁵ on epidemics among drug addicts, indicating that falciparum malaria was a problem here even before the war. It is to be expected that it may assume greater than pre-war magnitude now that the troops have returned and since overseas air transport has greatly increased the danger of foreign-incurred infections.

The pathologic changes in the various organs in 50 cases of falciparum malaria are described in detail. In this series "localization" or concentration of parasites occurs only in the spleen, liver, and bone marrow. Parasitized erythrocytes have been found to be otherwise uniformly distributed in other organs, even though the clinical symptoms may point to one primarily. The theory of *selective localization* of parasitized cells, in the author's opinion, cannot by itself, account for the protean clinical phenomena so characteristic of falciparum malaria.

Tropical Diseases—Col. J. E. Ash, M.C., and Dr. Spitz⁶ present in an "Atlas of Tropical Diseases" excellent pictorial coverage, distribution maps and diagrams of the life cycles of the causative organisms of all the primary tropical diseases as well as many other diseases common in, but not necessarily confined to, the tropics. As this volume was published over a year ago no further mention will be made of tropical diseases.

Virus Diseases—Col. Balduin Lucke in 3 reports,⁷⁻⁹ and Col. Lucke and Col. Tracy Mallory in one joint report¹⁰ on epidemic hepatitis discuss the clinical picture, etiology, epidemiology.

and pathologic anatomy in fatal and recovered cases, and summarize the present knowledge of the pathologic physiology in a total of 338 cases. Epidemic hepatitis has been recorded during every war for the past 100 years, but is not limited to wars or armies. It is endemic throughout the world; occurs in all races and in all ages, although most commonly in children and young adults. Outbreaks may develop wherever large groups of susceptible people are brought into close contact. Since World War I the disease has been on the increase, and latest reports¹⁰ also indicate an increase in severity.

Many terms have been used to describe this disease. Recent advances in knowledge of its virus nature suggest that the confusion may be resolved by the general adoption of the term "virus hepatitis."

The virus has not as yet been cultivated, nor has an animal other than man been found susceptible. At present the only means of demonstrating the virus is by human transmission. The virus has been shown to exist in the blood, feces, urine, and nasal washings. Under natural conditions it is probably transmitted either through the alimentary tract by contaminated food or water, or through the nasopharynx by droplet infection. Under artificial conditions the disease may be transmitted by parenteral injections of whole blood, plasma, or serum from persons harboring the disease; thus, epidemiologic variants may be recognized—naturally occurring hepatitis and inoculation hepatitis. The latter form is of particular public health interest because it is the present belief that definite lesions exist before clinical symptoms first become manifest. This is particularly true if jaundice is used as a clinical guide, for its duration or degree, presence, or absence, is not a measure of the severity of hepatic involvement. Accordingly, it would be possible to

take blood from a person in the very early stage of the disease and unknowingly use it in parenteral therapy.

The duration of the disease in fatal cases during the 1942 epidemic in the United States Army was usually from 4 to 6 weeks. During the past 2 years, the majority of fatal cases have been running a more fulminant course with a duration of less than 10 days. In approximately 0.3 per cent the disease ends fatally.

In the non-fatal cases, the structure of the liver has been studied in patients dying as a result of accident⁹ 2 weeks to 3 years after the initial attack. In none of the cases was there evidence that the disease was progressing toward a cirrhotic state. The conclusion is that complete restoration of hepatic parenchyma occurs in the vast majority of non-fatal cases of hepatitis.

Fungus Diseases — Prior to World War II a mere acquaintance with coccidioidomycosis usually had been considered sufficient for the physician outside of the endemic areas. That this is no longer true is obvious from the fact that this disease occurred in approximately 6,000 members of the armed forces in clinically recognizable form and in probably a far greater number as a subclinical infection. These patients have been scattered literally throughout the world. Dr. W. D. Forbus, resident consultant, reports a study of the material from 95 cases of the disseminated type of coccidioidomycosis¹¹ with special emphasis on the pathogenesis.

Coccidioidomycosis is primarily and predominantly a pulmonary disease, the mortality of which is negligible. When death occurs, Forbus believes, it is always associated with an endogenous reinfection. The residual pulmonary lesions of clinically healed cases contain vegetative organisms in all stages of development. These residual foci may serve as the source of disseminated in-

fection by bronchiolar ulceration and aspiration or by vascular dissemination months or years after evidence of pulmonary disease has disappeared.

Disseminated, secondary reinfections will continue to occur in members of the armed forces who were trained in the areas of the Southwest for approximately ten years and will cause a number of deaths. The author does not consider it likely that coccidioidomycosis will spread to non-endemic areas.

Tuberculosis—Col. Joseph D. Aronson¹² in an analysis of the occurrence and anatomic characteristics of fatal tuberculosis in the United States Army during World War II notes the following interesting statistical comparison. During World War II the mortality from tuberculosis in the United States Army, per 100,000, was 6.7, while among the civilian population during 1940 the rate was 47.7. In World War I the incidence of fatal cases among military personnel was 65.9, and in the civilian population in 1920 it was 151.4 per 100,000.

Infectious Mononucleosis—Major E. B. Smith, M.C., and Lt. Col. R. P. Custer, M.C., report an interesting complication in a study of 7 cases of rupture of the spleen in infectious mononucleosis. The authors ascribe the weakening of the splenic capsule prior to rupture to dilution and even dissolution of the capsule and trabeculae, the result of a cellular reaction of varying intensity. The time element is of interest to the examining physician. Rupture occurred in all cases between the 14th and 21st days of illness. The relationship between minor trauma and rupture is stressed. Simple palpation, climbing into bed, jarring or twisting, or straining at stool are listed as precipitating factors.

The authors recommend that when infectious mononucleosis is suspected, palpation be avoided, particularly after the 8th to 10th day of illness, and

that diagnosis be established by the more certain means available.

Other diseases of infectious nature of interest to public health physicians have been reported by Major Webb Haymaker¹⁴ in "Infections of the Central Nervous System Following Tooth Extractions," by Major J. E. Ehrlich, M.C.,¹⁵ in "Erysipelothrix rhusiopathiae or Swine Influenza in Man," and by Majors Jones and Davis¹⁶ in "Leptospirosis in War Dogs."

DISEASES DUE TO PHYSICAL, MECHANICAL, AND CHEMICAL INJURIES

Under the conditions of modern warfare, it is natural that diseases due to mechanical, physical, and chemical agents should provide the largest volume of material for study. During peacetime such agents are under adequate control, or are so limited in use as to make it difficult to obtain sufficient material for detailed study. During World War II, these agents ranged all the way from the radiation incident to the atomic bomb through modern therapeutic agents to frank poisons.

Physical Agents—Radiation, Heat, Cold, Anoxia:

Radiation Disease—The injury incident to the gamma radiation of the atomic bomb is not new, but surely the number of persons so injured is unprecedented. The follow-up study of such a group not only offers great opportunities for research but is essential, from a public health standpoint, if proper control methods are to be found.

Work on the report of the "Joint Committee for the Investigation of the Effects of the Atomic Bomb in Japan"¹⁷ has recently been completed at the Army Institute of Pathology. After necessary War Department review, it will be released for publication. The public health aspects are difficult to comprehend fully. The genetic-aftereffects, the carcinogenic effects, and

the industrial medical problems that are presented by the production and potential use of the atomic bomb are but a few of the extensive fields that will require study. The carcinogenic effects of similar agents are known, so it is logical to expect an increase in certain types of neoplastic disease.

To aid in the continuation of the original work and in the initiation of new studies, all related records are being retained as a unit at the Army Institute of Pathology. This material will be available to interested individuals and groups subject to the policies of the War Department. *Injuries due to heat*,^{18, 19} *cold*,^{20, 21} and *anoxia*²²⁻²⁴ are also reported. In non-fatal cases of heat stroke cerebral and cerebellar lesions, believed to be irreversible, occur and serve as an adequate pathologic basis for the cerebellar and mental sequelae which have been reported. In cold injuries the presence of thrombosis of the agglutinative type provides a rational basis for heparin therapy. The effects of chronic anoxia in man have yet to be evaluated. However, with the advance in high altitude and long range air travel, the possible dangers of acute and chronic cerebral asphyxiation should be kept in mind. A follow-up study of non-fatal cases will require a patient screening of the records of hundreds of air corps combat veterans in the hope of evaluating the as yet unknown residua. The Army Institute of Pathology serving as the Central Laboratory for the Veterans' Administration, will be able to render assistance in such studies.

Sudden death—Dr. Alan Moritz, Resident Consultant, and Capt. Norman Zamcheck, M.C.²⁵ present an analysis of the natural causes of sudden death in 1,100 soldiers. The authors list heart disease, intracranial hemorrhage, and meningococcemia as the three principal causes. Meningococcemia, as a cause of sudden death has not been sufficiently

emphasized. The authors point out the significance of degenerative changes in the adrenal cortex in this disease.

Homicide and suicide—Capt. Norman Zamcheck, M. C., and Mr. Murray Geisler, Statistician,²⁵ report a review of 1,100 suicides and 700 homicides occurring in soldiers under non-battle conditions. This large series demonstrates the applicability of the statistical method for differentiating between homicide and suicide. They correlate such factors as age, race, military status, time of day, day of week, weapon used, and site of injury.

Chemical Injuries: Sulfonamides—Ethylene Glycol—The following list (Table 1) is presented as a simple compilation of the various chemical agents listed in the Institute files. Time has permitted detailed study of this material in only a few instances.

Ethylene Glycol—Lt. Col. C. A. Pons and Lt. Col. R. P. Custer, M.C.,²⁷ report a clinicopathologic study of 18 fatal cases of acute ethylene glycol poisoning (anti-freeze intoxication) with detailed description of the histopathologic changes in the kidney and brain. Use is made of histologic examination with polarized light to emphasize the extensive double refractile crystallosis with calcium oxalate in the kidney and brain. The crystal formation is regarded as due to oxidation of ethylene glycol to oxalic acid and deposition as calcium oxalate.

Symptoms referable to the central nervous system were the most prominent part of the clinical picture. This is in keeping with the histologic findings in all 18 cases which showed focal hemorrhage and in some instances actual chemical meningo-encephalitis. Crystals, analogous to the oxalate deposits in the kidneys, were observed in a few of the engorged vessels at the point of contact between tissues and cerebrospinal fluid.

Sulfa Injury—Lt. Col. A. J. French,

M.C., reports on the study of hypersensitivity in the pathogenesis of the histopathologic changes associated with sulfonamide therapy.²⁸ Of approximately 500 cases of sulfonamide reaction studied, 76 were considered uncomplicated by other disease factors and the histologic changes of these cases are given in detail.

Evidence of individual susceptibility to initial and repeated courses of sulfonamide drugs, which has accumulated in the literature, is substantiated by this series of cases.

Sensitization of large groups of patients with prophylactic doses of sulfonamide may result in an increase in the number of histopathologic lesions encountered at autopsy. The accurate evaluation of the residual changes will require autopsy follow-up in cases with previous severe but non-fatal "sulfonamide sickness." Increased caution must be observed in prophylactic and thera-

peutic use of sulfonamide for minor infections.

Lower Nephron Nephrosis—In any highly industrialized country lower nephron nephrosis will continue to be a constant problem, principally in the field of industrial medicine, but also in general medical practice, where many of the precipitating factors are complications of routine therapy.

This syndrome was the most frequent form of fatal kidney disorder encountered among military personnel during the war. Among 427 battle casualties dying in the hospital the incidence was 18.6 per cent.

Col. Balduin Lucke reports a study of 538 fatal cases of this syndrome,²⁹ characterized by oliguria, heme pigment excretion, azotemia, hypertension, and uremia which developed in a variety of conditions associated with the destruction of tissues or intravascular hemolysis. These include crushing injuries,

nontraumatic muscular ischemia, uteroplacental damage, burns, transfusions with incompatible blood, blackwater fever and other types of intravascular hemolysis, heat stroke, sulfonamide intoxication, alkalosis, poisoning with vegetable and chemical agents. Once the characteristic symptoms set in, the mortality is high. Death usually occurs within 10 days.

Specific lesions occur in the kidney. The essential changes are selectively distributed over the lower segment of the nephron and comprise focal degeneration or necrosis, presence of pigmented protein casts, secondary inflammatory reaction in the surrounding stroma and thrombosis of thin-walled veins. The pathogenesis of the lesion has not yet been established.

The relation of symptoms to lesions is likewise incompletely known. It is probable that resorption of glomerular filtrate through injured segments of the lower nephron plays a very important part in the development of renal insufficiency.

Lower nephron nephrosis is not always fatal. Evidence is accumulating which shows residual changes in the kidneys indicative of earlier non-fatal lower nephron involvement. This is another problem that will require review of a large number of accidental deaths, if material, free of other diseases, is to be collected for study.

NEOPLASTIC DISEASES

Col. Ash has referred to the extensive material on bladder, kidney, prostate, lung, and skin tumors. In addition, Major Nathan B. Friedman and Dr. Robert A. Moore, resident consultant,³⁰ report on 922 cases of tumors of the testicle. The number of cases on file has now increased to 1,054 and follow-up is possible in approximately 850 of these. The result of this study has been a clarification of teratologic aspects and classifications.

Some of the phenomena encountered in this interesting group of tumors have spectacular implications; for example, the spontaneous regression of some of the malignant tumors and the differentiation of a malignant into a benign neoplasm. Especially striking from the public health viewpoint has been the long delay between the first symptoms of a testicular swelling and the removal of the tumor. Diagnoses of all sorts of inflammation, hydrocele and epididymitis, were made months before the diagnosis of tumor was arrived at. As part of the public health cancer programs, all cases of swelling of the testis should be considered first as possible tumor. Since one group of them, the seminomas or germinomas, which make up at least one-third of the series (307 cases), are highly radiosensitive and apparently curable by surgery and radiation, considerable saving of life may be expected by prompt action.

Hodgkin's Disease—Lt. Col. William E. Bernhardt and Lt. Col. R. P. Custer³⁸ report on the study of 700 cases of Hodgkin's disease; this large series, consisting of 500 cases with serial biopsies and 200 autopsies, provides sufficient material for a detailed study of the minor variations. The transition from para-granulomatous to granulomatous form to frank sarcoma of lymphoid or reticulum cell type is clearly established, and the relationship to giant follicular lymphoblastoma demonstrated. In a few cases of this large series it was possible to show a retrograde transition from sarcoma to granuloma. The authors suspect that Hodgkin's disease is a viral neoplasm.

In addition to these studies, tumor surveys have been completed covering intracranial neoplasms,^{31, 32} gastrointestinal tumors,³³ teratomas of the anterior mediastinum,³⁴ odontogenic tumors,³⁵ and others.

Coronary Artery Disease—As part of a continuing study of various aspects of

TABLE 2

Coccidioidomycosis	11	Total	1,402
Blastomycosis	2		
Actinomycosis	1		
Torulosis	1		

cardiac diseases, Dr. Wallace Yater, resident consultant, Major Wilson Brown, and associates³⁶ report the first paper of a series. In a statistical and clinicopathologic study of 443 cases of coronary disease, the authors stress points that are of special interest to medical examiners, industrial and induction board physicians, and others. Coronary artery disease as the cause of sudden death should be carefully searched for in all cases if the age of the patient is 20 years of age or more.

Myocarditis—It is rarely possible under peacetime conditions to collect a sufficiently large series of cases of inflammation of the heart to allow a broad study of the numerous etiologic possibilities. This is especially true in the younger age groups. The Army policy of centralizing its tissue pathology has made such a study and similar future

studies possible. Lt. Col. Ira Gore, Dr. Otto Saphir, resident consultant, and associates³⁷ are basing their studies on 1,402 cases of myocarditis associated with many different diseases (Table 2).

Since rheumatic heart disease was a cause for rejection at the time of induction their series shows only 130 cases of rheumatic carditis, leaving 90 per cent of the series due to other causes. Clinical myocardial involvement had not been suspected in the majority of this large group.

PROFESSIONAL RECORDS

In view of the potentialities of a collection of 103,000 cases, probably representing at least 300,000 diagnoses, since Pearl Harbor alone, it is natural to suppose an interest in the method used to record diagnoses, in the use of this material for teaching, and the

availability of these records to interested persons or groups. To handle the exceptionally heavy volume of cases it became obvious that standardization of diagnosis and utilization of modern mechanical methods were required. The *Standard Nomenclature of Disease* was selected as a standard code because of its widespread use and adaptability to machine records. Basic International Business Machines for punch cards were selected to handle the punching and sorting. Data, such as the case number, type of materials in the files, i.e., protocols, slides, blocks, tissue, etc., also age, race, sex, global area in which disease occurred, military status, duration of disease, treatment, operations, and type of trauma were placed in the first 22 lines of the standard 80 line IBM card. The remainder of the card, lines 23 to 80, were reserved for 7 diagnoses of 8 digits each. Additional cards for diagnoses are used as required.

It must be emphasized that the procedure here outlined was adopted as a rapid means of finding cards of a given diagnosis along with a maximum amount of clinical and administrative data. Thus, in a few minutes, a series of cases having many factors in common can be selected for further study. Special histopathologic or experimental studies having a wide range of individualized data are not adaptable to a single coding procedure and therefore must be handled as separate coding problems.

TEACHING MATERIAL

During the early part of the war when the need for a rapid expansion of knowledge of tropical diseases was necessary, the Institute, with the help of the Markel Foundation, prepared and forwarded to all medical schools of the United States and Canada comprehensive sets of colored lantern slides, microscope slides, paraffin blocks and tissues. This work was an expansion of a decentralized teaching program of the

American Registry of Pathology which was started many years earlier. Further expansion of these facilities is continuing. There are at this time 787 teaching sets, covering 80 subjects, available for loan through the American Registry of Pathology. New histology slide, lantern slide, and film strip collections on pertinent subjects are in preparation.

POLICY AND PROCEDURE FOR USE OF PATHOLOGIC MATERIAL

Now that the processing of the war-accumulated material is slowly drawing to a close, study of the best method of making this material generally available and insuring its maximum utilization is under way. For many years the Acts of Congress of 1892 and 1905 and Army Regulation 40-410 in its various revisions have emphasized the availability of the medical resources of the Institute (formerly the Army Medical Museum). However, prior to World War I, diversification was limited and accordingly the appeal to the medical profession as a whole was slight. During World War II the selected material forwarded by hundreds of field units has grown into the largest diversified collection of usual and unusual diseases known to medicine. Primary processing, a formidable task in itself, has kept step with the arrival of an average of nearly 3,000 cases per month for the year 1945. Detailed analysis has been completed on some of the important material; nevertheless, there remains a vast untapped store of unanalyzed material

that will require many years of patient, careful, and coöperative effort for full exploitation. Many persons have requested permission to use this material. In so far as possible, full availability will be granted to qualified persons. To handle requests a review board has been appointed by the Director.

At the present and in the immediate future, limitations of space and personnel for other than basic review, teaching, and research will impose some restrictions on the use of the Institute file. However, it is expected that personnel adjustments and other arrangements necessary to develop the facilities for study and investigation by other than the immediate staff of the Institute will keep pace with applications for use of the Army Institute of Pathology material.

Wartime Army Medical Laboratory Activities

Wartime Activities of the Army Veterinary Laboratories *

RAYMOND RANDALL, COLONEL, V.C., U.S.A.

Director, Army Veterinary School, Medical Department Professional Service Schools, Army Medical Center, Washington, D. C.

IN presenting the wartime veterinary laboratory activities of the Army, it is believed appropriate first to give a brief description of the functions of the Army Veterinary Service. As a component of the Medical Department, it is charged with duties falling under two definite heads, those with respect to the conservation of the health of public animals and the care of these animals when disabled, and those concerned with the inspection of meat, meat food, and dairy products required by the Army.

The dual nature of the functions of the veterinary service, concerning animals on one hand and human beings on the other, with the recognition that animal diseases have a close connection with human disease, requires a close relationship with the general service of the Medical Department. This relationship is reflected in the scope of the wartime veterinary laboratory activities that included: (1) the chemical and bacteriological analysis of meat, meat food and dairy products, and research activities pertaining to this field; (2) clinical diagnostic laboratory procedures; (3) research on the control of animal diseases; and (4) 'research, de-

velopment, and the large scale production of biologics.

Of the 2,200 veterinary officers and 5,000 enlisted men who constituted the wartime Army veterinary service, approximately 100 officers and a proportionate number of enlisted and civilian technicians were required to perform these laboratory functions.

Since veterinary laboratory service was required not only by the Medical Department but also by the Quartermaster Corps and the Chemical Warfare Service, there existed three types of laboratory and research work; namely, medical, quartermaster, and chemical warfare. While some veterinary personnel were engaged solely in the performance of routine laboratory procedures and others in development and research work, most of the members of the Corps engaged in both types of activities. Certain of the investigations dealt with research and development activities pertaining to biological warfare and some were in connection with military missions.

SERVICE COMMAND LABORATORIES

To meet the requirements for laboratory service in the United States, nine service command laboratories were established. To each was assigned a veterinary section consisting of one or more veterinary officers and several

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 14, 1946.

qualified enlisted and civilian technicians. Veterinary laboratory service for the Third Service Command was conducted at the Army Veterinary School, Army Medical Center, Washington, D. C.

The major activities of the veterinary sections of these laboratories involved chemical and bacteriological examinations of meat, meat food, and dairy products. Such examinations were desired to determine whether the foods met specifications and contract requirements as to type and quality.

Approximately 225,000 food specimens of animal origin were received for analysis during World War II. They were representative samples from the more than 30,000,000 lbs. of meat and dairy products which were being inspected daily by Army veterinary personnel at the source of supply at the time the war ended. The samples included such foods as canned meat products, desiccated eggs, fresh, evaporated, powdered, and frozen milk, frozen or powdered ice cream, butter, and cheese. As an example of the increase in variety of canned meat products which were supplied to our soldiers as the war progressed, it may be pointed out that when we entered World War II there were only six canned meat dishes in the Army ration, but by the end of 1944, this had been increased to fifty.

A valuable contribution to the war effort was the application of adequate laboratory control measures which insured the wholesomeness and safety of the 65,000,000 lbs. of fluid milk which were required each month, at the peak, to provide every man in training in the United States with at least $\frac{1}{2}$ pint of fresh milk daily. The development and improvement of methods for the production of dried eggs and powdered milk resulted, in part, from Army laboratory investigations and research findings.

The chemical examinations of food of

animal origin included quantitative analyses for protein, salt, calcium, phosphorus, acidity, moisture, and fat. Gravimetric analyses were made for moisture, crude fiber, total solids, cereal, sugar, and net weight and colorimetric analyses for sodium nitrite and sodium nitrate. Gasometric analyses were made for carbon dioxide and oxygen in both dried milk and desiccated eggs.

The spectrophotometric method of analysis was employed to determine the copper and iron content of dried food products. The palatability index of desiccated eggs was determined by fluorometric analyses. The keeping qualities of lard and shortening were judged by the active oxygen test.

Bacteriological examinations of foods of animal origin included standard plate counts, coliform counts, yeast and mold counts, examination of canned foods for sterility and the identification and typing of microorganisms associated with canned food spoilage.

In the interests of uniformity of methods and accuracy of laboratory results, some of the Service Command laboratories coöperated with the laboratories of the egg, dairy, and meat industries in various studies along bacteriological and chemical lines. These studies were of great value in promoting a better understanding between the Army and commercial food industries.

In addition to the chemical and bacteriological examination of foods of animal origin, these laboratories were equipped to perform complement-fixation tests for glanders, equine infectious abortion, and trypanosomiasis, agglutination tests for brucellosis, and virus neutralization tests. Microscopic examinations and animal inoculation tests were made for rabies. Examination for the presence of pathogenic bacteria were carried out on animal specimens and histopathological examinations were made of tumors and other tissues.

One of the important functions of the veterinary section of Army laboratories, in both the United States and those overseas, was the procurement, breeding, and maintenance of stocks of various laboratory animals. This task which was of special importance to Army and general laboratories overseas was most difficult to perform under field conditions, where climate, facilities, and feed were often unsuitable and rarely conducive to the breeding and maintenance of laboratory animals.

OVERSEAS VETERINARY LABORATORY SERVICE

There was a total of nineteen Army medical laboratories and four medical general laboratories organized and equipped for laboratory operations in the held under wartime conditions. All of these units, with the exception of the 14th Medical Laboratory, were equipped and trained in the United States before deployment overseas.

Each of these laboratories included a veterinary section whose objectives and activities were the same as those of Service Command laboratories in the United States.

Due to the global type of warfare, the veterinary activities of these laboratories varied widely according to the types of animal diseases which were present and the quality and quantity of available perishable foodstuffs.

A veterinary laboratory officer did not confine his entire time and field of endeavor to matters strictly pertaining to veterinary science. He was a member of a highly specialized team whose mission it was to furnish a complete laboratory service for a given area. Consequently he had a wide variety of assignments. For instance, the veterinary section of a Mediterranean Theater laboratory was the Salmonella typing center for the theater and developed a polyvalent type "O" Salmonella antiserum for the rapid detec-

tion of Salmonella organisms. In another laboratory located in the Pacific area, the veterinary section participated in the study of scrub typhus and poliomyelitis. The veterinary officer of a European Theater laboratory was assigned for a time to work with the Combined Intelligence Office.

VETERINARY RESEARCH LABORATORY

The Army Veterinary Research Laboratory, originally located at the Front Royal Quartermaster Depot and now located at the Quartermaster Remount Depot, Fort Robinson, Nebraska, was activated in 1939 to study periodic ophthalmia of horses and equine influenza.

The many theories of the etiology of periodic ophthalmia were thoroughly explored and it was concluded that heredity, bacterial and virus infections, and helminth infestation were of no significance. Extensive nutritional studies revealed that riboflavin was a nutritional factor involved and that supplementation of the feed ration with riboflavin was an effective means for the prevention of the disease.

Equine influenza was studied with the primary objective of developing means of prevention of morbidity and mortality of this disease in Army animals. The virus of equine influenza was found to be antigenically distinct from the viruses of human influenza, swine influenza, and canine distemper. Of prime importance was the discovery that the virus could be attenuated and that such a strain could be used as a vaccine to produce a mild and harmless disease which was followed by solid immunity.

This laboratory, at the direction of the Surgeon General, and in coöperation with the Rockefeller Foundation, endeavored to transmit infectious serum jaundice of man to horses. Yellow fever vaccines suspected of having caused the disease in man were em-

ployed. The experiment was discontinued when it was found that horses were not susceptible to the virus.

The establishment of a War Dog Reception and Training Center at the Front Royal Quartermaster Depot provided additional research problems for the Army Research Laboratory.

Canine leptospirosis presented a particular public health problem in that this disease is transmissible from infected dogs to man. An effective program for the control of this disease among Army war dogs was established by eliminating all dogs whose serum reacted to the plate agglutination test for leptospirosis.

The high incidence of *Dirofilaria immitis* in war dogs, serving in many parts of the United States and overseas presented a serious problem. Compound antimony has so far offered the greatest promise of treating infected animals. The study of the mechanism of the action of these compounds, their distribution in the body, and their toxicity have been of advantage in the treatment of filariasis in man.

CHEMICAL WARFARE SERVICE

Veterinary laboratory personnel were engaged in the study of the toxicological effects of chemical warfare agents on animals and in certain anti-biological warfare projects in connection with the protection of food supplies and the livestock industry.

Through coöperative studies made by the Chemical Warfare Service, the Medical Department and the Quartermaster Corps food was packaged in a manner that would minimize the chances of contamination in the event of chemical attack by the enemy. This method was more efficient and satisfactory than food decontamination measures. Further, a field service kit was developed for the rapid detection of toxic quantities of chemical contaminations of food.

Approximately twenty veterinarians

served in the Special Projects Division of the Chemical Warfare Service in the development of Biological Warfare including both the defensive and offensive phases. Certain of these findings will have a post-war application that will be of benefit to mankind.

Through the Joint United States-Canadian Commission and the Chemical Warfare Service, a War Disease Control Station was established on Grosse Isle, Province of Quebec, Canada, in 1942. The purpose of this project was to develop means by which the cattle of the North American continent could be protected against rinderpest if the disease should gain entrance. This project was staffed by six officers of the U. S. Army Veterinary Corps, one from the Medical Corps, U. S. Navy, and two scientists of the Canadian Army.

Rinderpest, a rapidly spreading virus disease, was at that time nonexistent in the Western Hemisphere and rigid quarantine and safety procedures were enforced to confine the disease to the experimental area.

The first objective of the Grosse Isle group was to prepare an adequate supply of tissue vaccine, according to methods previously developed, which could be used to provide a ring of immunized animals around an epizootic area. The second objective was to investigate the possibility of developing an efficient vaccine that could be produced without the use of a large number of animals.

After completing their first objective, they developed an attenuated rinderpest vaccine from virus in embryonated eggs that would produce a solid and lasting immunity in cattle. The dried vaccine, packed in vacuum, will maintain its potency for as long as 15 months, when stored at a temperature of 2 to 5°C.

The avianized vaccine is now being extensively tested in one of the countries where the disease is enzootic. It has proved to be so attenuated that only

mild and negligible reactions are produced in native cattle which are more highly susceptible to the disease than European breeds.

PAN AMERICAN SANITARY BUREAU

Foreseeing the possible spread of serious animal contagions as a result of increased animal traffic on the new projected Pan American Highway which is routed from the United States through Mexico and the Central American countries, the officials of the Pan American Sanitary Bureau instigated an Army veterinary survey of the animal diseases in the Central American countries.

This constituted the first comprehensive study of the diseases of animals in this area. Suggestions were made to the representatives of these governments for improvement of animal livestock industries and for the sanitary control of animal diseases.

As a result of this investigation it was found that international sanitary control of animal diseases was of paramount importance to the success of the Pan American Highway as an overland route.

SURVEY OF MILK SUPPLY AT AN ADVANCED AMERICAN BASE

Due to the prevalence of undulant fever in the civilian population on an island in the Atlantic Ocean where American troops were based, an Army veterinarian was detailed in December, 1941, to make a survey of the milk supply.

It was found that the incidence of brucellosis in the dairy cattle was approximately 51.4 per cent and that less than one-half of the milk supply was pasteurized.

A calfhood vaccination program was initiated using the U. S. Department of Agriculture's Strain 19 avirulent culture of *Brucella abortus* to protect the cattle breeding industry against abortions. An adequate inspectional sys-

tem was set up for the sanitary control of dairy farms and milk plants. Compulsory pasteurization of all milk was instituted after an additional pasteurizing plant was installed to meet the increased needs.

No additional cases of undulant fever have been reported since the carrying out of this program.

ICELAND BASE COMMAND

With the approval and material assistance of the officials of the Government of Iceland, Army Veterinary Corps officers pioneered a veterinary laboratory in that country late in 1941. During the succeeding two years they contributed a most important public health service in improving the milk supply of Iceland, and in the fields of animal husbandry and veterinary research in connection with diseases prevalent in Icelandic domestic animals.

VETERINARY LABORATORY SERVICE WITH ALLIED MILITARY GOVERNMENT IN EUROPE

Following the invasion and subsequent occupation of Germany, Army Veterinary Corps officers investigated and assumed technical responsibility for the control of biologic production at the I. G. Farbenindustrie Behringwerke, Marburg, Germany. The animal colonies of this plant included approximately 1,600 horses, 138 calves, 165 sheep, 3 goats, 10 swine, and 1,800 rabbits. As of June, 1945, this establishment was reportedly producing 150 per cent over the pre-war level.

In Italy the main concern was the rehabilitation and recovery of the eleven government-owned and controlled, and three privately owned laboratories which had produced biologics for the prevention and treatment of animal diseases. To reactivate these laboratories it was necessary to furnish them various types of equipment and supplies, and large and small laboratory animals.

THE ARMY VETERINARY SCHOOL, ARMY MEDICAL CENTER, WASHINGTON, D. C.

In October, 1923, the Division of Laboratories, Army Veterinary School, was moved to its present location to become an integral part of the Army Medical Center which was established September 1, 1923. Prior to the war, in addition to its manufacture of biologics and research activities, it handled routine Army veterinary laboratory activities for the greater part of the United States. With the establishment of the nine Service Command laboratories in 1941, it took over the veterinary laboratory activities for the Third Service Command and in addition functioned as a control laboratory. The latter duties included the study of subcultures of all organisms associated with outbreaks of animal diseases investigated in service command laboratories, and coöperation with Service Command and industrial laboratories in the standardization of laboratory methods for the chemical and bacteriological examination of foods of animal origin.

Beginning in December, 1940, and throughout the emergency period, it conducted special graduate courses in clinical pathology for veterinary officers and courses for enlisted veterinary laboratory technicians. Thirty-nine veterinary officers completed the course in clinical pathology.

During the war period the Division of Veterinary Laboratories produced the following biologics for the entire Army: equine encephalomyelitis vaccine, both animal and human, infectious abortion bacterin, mallein, tuberculin, infectious abortion antigen, glanders antigen and *Brucella* antigens of both plate and tube types. It also prepared the following positive sera for complement-fixation and agglutination tests: glanders, equine infectious abortion, trypanosomiasis, and contagious abortion.

Since 1939 these laboratories have manufactured the chick embryo type

equine encephalomyelitis vaccine used annually to immunize all Army horses and mules. Since the inauguration of this program no properly vaccinated Army animal has contracted encephalomyelitis. In addition to improving the method for the preparation of this highly potent horse type vaccine, a vaccine has been perfected for use in human beings which contains only one-tenth of inert chick tissues present in the horse type vaccine.

Methods for the mass production of more purified and concentrated typhus vaccines prepared from infected yolk sacs of embryonated hens' eggs were studied in coöperation with members of the Virus and Rickettsial Laboratory, Army Medical School. This project was begun on August 14, 1942, and the innovations and findings that resulted were included in a special report which was submitted on November 18, 1942.

Methods for the freezing and storing of milk in the frozen state which renders it acceptable for use on thawing have been studied and the findings have been the subject of two papers that have been submitted for publication.

In 1941 the Eastern type equine encephalomyelitis virus was isolated at the Army Veterinary School from horse brain material originating in Texas. Previously, only the Western type virus had been known to exist west of the Appalachian Mountains—Alabama line, and in October, 1943, the Venezuelan type of equine encephalomyelitis virus was isolated from two fatal human cases which occurred in Trinidad. This was the first recorded instance of natural infection of man with this type virus, resulting in a fatal infection.

These laboratories also made the analyses for protein, fat, carbohydrates, and moisture of foodstuffs employed in the Army Medical School Project M 11-1 entitled "Nutritive Value of Expeditionary Ration."

Japanese B encephalitis vaccine of

chick embryo type was produced for the first time by mass production methods in these laboratories during the last five months of the fiscal year 1946. This project was in collaboration with the Division of Virus and Rickettsial Diseases, Army Medical School. The field trials of this chick embryo type vaccine were made during the past summer in Japan and Okinawa.

CONCLUSION

The fact that no serious outbreaks of

food-borne diseases occurred among our troops, and not a single serious epizootic among the thousands of horses, mules, dogs, and pigeons employed in military operations, was in no small part due to veterinary laboratory activities.

Further, laboratory research contributed methods for the control of exotic animal plagues, had they accidentally gained entrance to our continent, or had they been introduced intentionally as a means of biological warfare.

Devastated Library Needs

The American Book Center for War Devastated Libraries (Library of Congress, Washington, D. C.) recently issued a report of the first year of operation. The gist of it is to thank the 950 institutions and 2,800 individuals who have contributed books and periodicals, and the 25 agencies that have given more than \$100,000 in cash. It has thus been possible to ship nearly a million volumes of books, periodicals, and pamphlets to libraries in 34 foreign countries.

A few facts about the program: The Library of Congress has furnished space for the operation of preparing shipments for overseas which has required a staff of 30. Twenty-six per cent of the publications shipped were in the general

field of medicine, another 13 per cent in science other than medicine. Ten to 15 per cent of all volumes received at the shipping center have been discarded as of insufficient worth to justify shipping. Geographically every part of the country is represented in contributions but the American Book Center reports especially heavy contributions, considering their respective library resources, from Tennessee, North Carolina, Massachusetts, and California.

One last word: the need is still great and ABC suggests that America "cannot ignore its profound obligation to use its riches for the rebuilding of those physical and cultural institutions which were so grievously damaged by the war."

Wartime Army Medical Laboratory Activities

The Routine Virus and Rickettsial Diagnostic Laboratory *

HARRY PLOTZ, M.D.†

Formerly Chief, Division of Virus and Rickettsial Diseases, Army Medical School, Washington, D. C.

DURING the War years the Army developed a laboratory service for the diagnosis of virus and rickettsial diseases which was unique in military medicine. Indeed, this represented the first attempt either in military or civilian medicine to provide such a broad coverage for the diagnosis of diseases which are of tremendous importance to medicine in general. The service was developed from a small nucleus at the Army Medical School which gradually increased in size and then spread to include other laboratories in the Armies throughout the world. While the Division of Virus and Rickettsial Diseases at the Army Medical School remained the central reference laboratory for all diagnostic work performed during the war years, each Theater of Operations (European, Mediterranean, CBI, and Pacific) had laboratories which performed certain diagnostic tests for the troops in its command. Furthermore, as the Army expanded in the United States certain of the diagnostic functions were taken over by a few of the Service Command laboratories, such as those of the Fourth, Eighth, and Ninth Command areas.

Not only was the principle of a general routine diagnostic service for virus and rickettsial diseases new, but also many of the methods and materials used for this type of work were in the developmental stage when the laboratory at the Army Medical School began to function in January, 1941. A number of diagnostic procedures for important diseases had to be evaluated or developed as the war progressed. Even those tests which were sufficiently well standardized for immediate adoption required materials which were not available elsewhere. Therefore, these had to be manufactured at the Army Medical School. Eventually it was possible for some of the Medical General and Service Command Laboratories to make some of the necessary antigens and antisera, but certain of the required materials were supplied to them by the Division of Virus and Rickettsial Diseases of the Army Medical School.

An idea of the extent of the serological diagnostic work performed at the Army Medical School is evident from the following list of diseases which were under consideration. Among the neurotropic virus diseases were lymphocytic choriomeningitis, Eastern, Western, St. Louis, Japanese B, Russian spring and summer, West Nile, and herpes encephalitis. Other virus diseases examined were influenza, atypical pneumonia, mumps, and those due to the

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 14, 1946.

† Died January 6, 1947.

lymphogranuloma venereum-psittacosis group of agents. In the rickettsial field, specific complement-fixation and rickettsial agglutination tests were regularly performed for epidemic and murine typhus, Rocky Mountain spotted fever, Q fever, and on occasion for the less common rickettsial diseases. Besides these serological tests, attempt at strain isolation and identification was made in many of the above diseases.

Before the Laboratory could provide useful service to medical officers in the field, it was necessary to define the problems pertaining to virus and rickettsial diseases, to teach the value of diagnostic procedures, and to describe the necessary information regarding the collecting and shipping of materials for study. This was accomplished in two ways: Circular letters, containing the necessary information, were prepared and widely circulated by the Surgeon General's Office. Training, by means of lectures and demonstrations, was provided to some 2,000 officers in the course in tropical medicine given at the Army Medical School.

It was not only important to train doctors in the value of the diagnostic services available, but in addition it was necessary to train laboratory personnel, both technical and professional, to perform the required work. Before the war, relatively few scientific workers had experience in this field and very few of these became available to the Army. The extent of the laboratory training program is evident from the fact that practically all of the officers in the Army at the close of the war who performed virus and rickettsial work had received some period of training at the Army Medical School.

Investigation was actively associated with the diagnostic laboratory. In this manner diagnostic methods were studied and evaluated and new techniques were devised. This is illustrated in the work of a number of our Army laboratories.

The Fifth and Ninth Service Command Laboratories in the United States and the First Medical General Laboratory in Europe, as well as the Eighteenth Medical General Laboratory in Hawaii, contributed to our knowledge of influenza. Investigations on epidemic and scrub typhus were followed in the First Medical General Laboratory and the Nineteenth Medical General Laboratory. Extensive studies on hepatitis were carried out in the Fifteenth Medical General Laboratory where, in addition, significant contributions to our knowledge of Q fever were obtained.

Some of the more important results of investigations carried out at the Army Medical School were as follows. Specific serological tests for the diagnosis of a number of rickettsial infections of man were developed in the Division of Virus and Rickettsial Diseases. Although the techniques for the identification of infections with epidemic and murine typhus were the most important from a military point of view, those for Rocky Mountain spotted fever, boutonneuse fever, and South African tick bite fever were also valuable. The tests for typhus fever which were developed in this Division became standard diagnostic procedures used throughout the Army and by the members of the United States of America Typhus Commission. Furthermore, they have proved extremely useful for survey purposes in determining the type of typhus prevalent in a given area. In addition to information of direct military importance obtained from such studies, the Division conducted surveys in Latin America in coöperation with the Office of Inter-American Affairs which enhanced our knowledge of the type of typhus found in several countries.

While no entirely new diagnostic methods for the virus diseases were developed in the Division, a number of the existing methods were improved and standardized. These included serologic

tests for the lymphogranuloma venereum-psittacosis group of agents, for the various members of the group of neurotropic viruses, for the influenza viruses, and for the mumps virus. Valuable information on the occurrence of these infections in Army personnel was obtained by application of these methods.

Preventive measures have dealt principally with the development of vaccines for immunization against epidemic and scrub typhus and Japanese encephalitis, all of which are of great military importance. In addition, significant advances have been made in the study of chemotherapeutic agents active against rickettsiae.

Early in 1941 the Division emphasized the inadequacy of the typhus vaccine then employed by the Army. As a result of comparative studies with various types of vaccine, the need was pointed out for increasing the concentration of antigenic materials in the vaccine to be used by our troops. In constant close contact with other laboratories engaged in this problem, the Division contributed to the development of a typhus vaccine rich in rickettsiae and soluble antigen. This product was adopted by the Army late in 1942; but not until 1944 had sufficient evidence accumulated to indicate that the new vaccine, plus other control measures, was adequate to protect an army operating in a typhus infected area. During this interval the Division continued to study means of improving the typhus vaccine adopted in 1942. All of our troops overseas were immunized and, while a few mild cases of epidemic typhus occurred in these immunized individuals, not a single American soldier died of epidemic typhus fever during World War II.

As epidemic typhus decreased in importance to the American armies, scrub typhus assumed increasing significance. During the summer of 1944

potent vaccines were prepared both here and elsewhere. None of the methods were well suited to large-scale commercial manufacture and the war ended before any of the three types of vaccine was given an adequate field trial.

In the Pacific Theater, Japanese B encephalitis has affected our troops and may continue to be a problem during the period of occupation. A vaccine against this disease, prepared from embryonated eggs, has been developed recently in the Division.

As a result of the war experience in the Division of Virus and Rickettsial Diseases, a number of facts of general importance have been learned:

1. It is evident that medical training in our schools has been notably deficient in the clinical teaching of virus and rickettsial diseases. Greater emphasis must be placed on this important group of infectious diseases by our universities.
2. The diagnostic procedures now employed for virus and rickettsial diseases have reached the stage of development where they can in many instances be employed by competent bacteriological and serological laboratories associated with universities and public health organizations. The training of personnel in these methods is essential. The dissemination of information and the application by civilian laboratories is to be encouraged.
3. Diagnostic work for the virus and rickettsial diseases is still expensive, both as regards time and money, and requires personnel and equipment which should be devoted, at least in part, to investigative work in these fields. It has been pointed out that each of the Army laboratories doing virus and rickettsial work combined diagnosis and research. This combination is to be encouraged. Indeed, it is essential for the advancement of knowledge in this important field.
4. The experience of all of the lab-

oratories doing this type of work has been that one of the main difficulties centers around obtaining the proper specimens for diagnostic tests and their transportation in a satisfactory manner. This can be accomplished by an educational program. The principles which should be employed have been learned and applied on a large scale in the Army and the experience is available to others.

5. The continuous active enthusiastic

support of the program of diagnosis and investigation of virus and rickettsial diseases by the Army has indicated the usefulness of such medical service to a military organization. A number of universities and public health organizations have begun plans for providing diagnostic facilities for virus and rickettsial diseases, along the lines developed by the Army. These efforts should be encouraged in every way possible.

Attention: Sanitary Corps Officers

A history of the Sanitary Corps during the last war is being compiled by Colonel M. J. Blew, Sn.C. Colonel Blew has volunteered his services in preparing a record of the accomplishment of the Corps. All former Sanitary Corps officers, including those still on active duty, are asked to communicate with Colonel Blew giving their rank, date called to active duty, and date of separation, present rank or rank on separation, specialty in the Corps

(engineering, entomology, parasitology, bacteriology, chemistry, nutrition, etc.), a résumé of pertinent facts regarding active duty assignments, awards or commendations, academic and professional degrees, professional and honorary society affiliations, and state of registration or certification.

Material should be sent to Colonel M. J. Blew, Sn.C., National Society of Professional Engineers, 1359 Connecticut Ave., N.W., Washington 6, D. C.

Wartime Army Medical Laboratory Activities

Development of *Shigella* Typing by Antigenic Analysis *

PHILIP R. CARLQUIST, MAJOR, PC, U.S.A.

Division of Bacteriology, Army Medical School, Washington, D. C.

UNTIL the work of Andrewes and Inman,¹ and Gettings² with the mannitol-fermenting organisms of the genus *Shigella* demonstrated antigenic differences within groups having the same biological pattern, it had been the custom to recognize species within the genus by the determination of their physiological characteristics only. The scheme established by Andrewes and Inman¹ was based on the recognition of four antigenic components of the Flexner group which permitted the differentiation of five races and two sub-races. This fundamental concept gained wide acceptance and was not challenged until Boyd³⁻⁶ determined the presence of six fractions of group antigenic components which were common to members of the Flexner group, and established the presence of other antigenic components which were type-specific. He also established six additional races, characterized only by type-specific antigen. Wheeler⁷ was unable to identify all the group antigenic components suggested by Boyd, but confirmed his work on the type-specific antigens. Weil, Black, and Farsetta⁸ proposed a new classification of the Flexner group of organisms based upon an analysis of major antigenic com-

ponents. This suggestion needs further investigation before it can be accepted as valid by the Army.

Recognizing the limitations encountered in the differentiation of these organisms through physiological study, the Division of Bacteriology of the Army Medical School began developing sera for the identification of members of the *Shigella* group in the early part of 1943. It was decided to prepare suitably absorbed sera for the slide agglutination technic as suggested by Wheeler.⁹ To supply the needs of all Army installations in the United States and the overseas theaters, it was essential to produce and absorb large volumes of sera. Previous experience had shown the necessity of producing four times the amount determined essential for each installation to make up for storage and loss in shipping.

Cultures from many collections and other sources were studied for conformance with the antigenic patterns recognized as standard. Each culture was lyophilized as soon as it was received at the Army Medical School in order to avoid changes in antigenic structure which might develop through serial transfer on culture media. Strains capable of producing high agglutinin titers were then utilized for the immunization of rabbits. All such cultures were harvested after less than 18 hours' incubation. Our experience has demon-

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 14, 1946.

strated that cultures over 18 hours old produce sera which contain increased quantities of nonspecific agglutinins. When trial bleedings demonstrated that the maximum development of agglutinins had occurred, the rabbits were exsanguinated. All concentrated sera were preserved in merthiolate (1:5,000) and allowed to "stabilize" at 5° C. for one month before absorption procedures were begun. These were carried out using dried *Shigellae* as the absorbing suspension.

In order to secure adequate quantities of absorbing organisms for such large volumes of sera, mass cultures in liquid medium were made. The medium for mass culture was dispensed in 33 liter lots and consisted of nicotinamide and calcium pantothenate as growth factors added to a 5 per cent dextrose, 2 per cent tryptose broth. The inoculum was prepared from a lyophilized culture of the desired strain which had been activated by a 24 hour incubation in 0.5 ml. veal infusion broth. A 1,000 ml. culture in tryptose broth, in the log phase of growth was used as the inoculum for the carboy. During the processing of the inoculum, continual purity checks were made. The carboy culture was incubated 18 hours with constant aeration and stirring. At appropriate intervals 5N-Na OH was added to maintain the pH at 7.4. The mass culture was heat-killed at 60° C. for 30 minutes, harvested with a Sharples centrifuge at 50,000 r.p.m., and resuspended in saline. This suspension was washed and reprecipitated with several volumes of acetone, after which it was dried, weighed, and stored at 5° C. until used. Yields were usually 50-60 gm. of dehydrated bacterial substance per 33 liter mass culture.

A scheme for the absorption of each antiserum was determined by the preliminary testing of a 1-10 dilution of the unabsorbed antiserum against at least one representative strain of each

known *Shigella* type, race, or variant. Antigens used to determine this pattern, as well as others used throughout the absorption, were live organisms washed from 18 hour slants in 2 ml. physiological saline. Results were not reliable when organisms were incubated for periods longer than 18 hours. Large glass plates, thoroughly cleansed and blocked off into small rectangular boxes with a soft wax pencil provided a stage on which many tests could be set up at the same time. The test was made by transferring a drop of antigen and a slightly larger drop of antiserum to a box on the slide. The slide was gently rocked for 5 minutes, and the agglutinations were read by transmitted light as strong, weak, or absent.

To conserve sera all trial absorptions were conducted on a micro scale. The primary absorption was carried out for the removal of the group components of the Flexner races.

A typical absorption was begun by weighing out 10 mg. of dried organisms (usually Flexner X or Y). These were suspended in 2 ml. of physiological saline, dispensed into micro tubes in 0.5, 0.4, 0.3, 0.2 and 0.1 ml. quantities and centrifugalized. After removal of the supernatant saline, 0.25 ml. of test antiserum was added to the sediment in each tube, thoroughly mixed, and immediately recentrifugalized. From this, the number of mg. per ml. necessary to remove the group agglutinins could be readily determined. If the quantity used was insufficient for complete removal of the cross-reacting antibodies, the procedure was repeated using increasing amounts (up to 100 mg.) of dried organisms until it was evident that no agglutinins for that particular organisms were present. Five to 10 ml. of antiserum, absorbed according to the above calculation was prepared at this point and absorption of the remaining nonspecific agglutinins was continued on the micro scale.

** Usually negative Requires heat to produce agglutination

* Non-specific (e.g. types X and Y) and rough strains usually agglutinate in Polyvalent A serum but not in the specific sera.

Many types were used to produce a specific serum. All trial absorptions were carefully controlled by testing with the homologous antigen to deter-

mine loss of type-specific components. The absorption formula was then checked on 5 ml. of 1:10 antiserum. Large lots of antisera were prepared

from the formula finally established by micro technic. Each lot of absorbed serum was tested against all *Shigella* organisms in the Army Medical School collection to determine its specificity and to rule out cross-reactions which might not have appeared in the preliminary testing. This final battery of antigens was composed of 360 strains of *Shigellae* representing every race, variant, and species available from all sources. Titers were established by checking a serum against all the homologous strains in the collection and using the weakest reaction as the maximal point. The actual titer of a serum was determined as the dilution two steps less than the maximum to compensate for deterioration and dilution. If preliminary titrations carried out in geometric progression indicated a titer of less than 1:80, the titration was repeated arithmetically with a common difference of 10. If the highest agglutination was 1:70, the dilution for use was 1:60 and the serum was bottled at 1:30. Such titers are of interest because they effected the conservation of sera. The sera distributed to Army installations for routine diagnostic tests were standardized to be effective when diluted with an equal volume of saline.

The components of the polyvalent sera were determined by the frequency of their occurrence as well as by their antigenic relationships. Flexner races, V, W, and Z, *Sh. sonnei*, and Boyd's 103, P119, and 88 were placed in group A, the remaining Boyd species in group B, and the rarer species, *Sh. dysenteriae*, *Sh. ambigua* and *Sachs Q771*, in group C. Cross-reactions were first absorbed from each component serum. Component sera were then pooled in appropriate proportions to bring about the agglutination of all organisms included in the group. Cross-reactions detected in the final testing were absorbed from the pooled lot. Whenever the reactions

were weak against one of the antigens, additional homologous serum was added until adequate agglutination occurred. All absorbed sera were preserved with 1-10,000 sodium merthiolate and were sufficiently potent to agglutinate specific organisms within 5 minutes when the slide agglutination test was used.

Although the components of the polyvalent sera were primarily selected on a basis of frequency, it should be noted that they followed accepted antigenic patterns. Polyvalent A serum agglutinated *Sh. flexneri* I to VI in Boyd's scheme, as well as all *Sh. sonnei* strains. Polyvalent C serum agglutinated the more common strains not identified with sera A or B. Thirty-one sera were produced for inclusion in the kits as outlined in the table.

Three types of kits were prepared for distribution. A simplified kit, supplied to general hospitals, regional station or station hospitals upon request, contained the three polyvalent sera, a trivalent serum for *Sh. paradysenteriae* Flexner V, W, and Z, and monovalent sera for Boyd 88, *Sh. sonnei*, *Sh. dysenteriae*, and *Sh. ambigua*. The polyvalent sera served as a screen before further differentiation was attempted. An organism positive in the polyvalent A serum could be tested in the trivalent VWZ, Boyd 88 and *Sh. sonnei* sera; if it was positive in polyvalent B serum no further breakdown was possible with this kit, but if it was positive in polyvalent C serum, it could be checked against both *Sh. dysenteriae* and *Sh. ambigua*.

A second and more complete kit was supplied to all Army Area Laboratories, to large general laboratories in overseas theaters and to certain other installations whose investigation work required a larger number of monovalent sera. This kit, in addition to all sera in the simplified kit, contained monovalent sera for the Flexner paradysenteriae V, W, and Z, Boyd's

103, P119, 170, P288, D1, P274, D19, and P143, *Sh. alkalescens* and *Sh. sonnei* (rough).

A third kit was available upon request to holders of the complete kit. This kit was composed of eight monovalent sera and included Sachs Q771, Q902, Q1030, Q1167, and Q454, *Sh. alkalescens*, type II, *Sh. madampensis*, and *Sh. ceylonensis*.

All individual sera were issued in glass vials with screw caps. Dropper assemblies were included for each vial to facilitate the dispensing of sera. Experience has shown that 1 ml. of serum, diluted with an equal volume of physiological saline, was sufficient for more than 100 tests. Instruction sheets describing the preparation of antigens and sera, the technic and interpretation of the tests, accompanied each kit.

In the production and absorption of these sera many interesting problems evolved and many avenues of future investigation were opened. It was discovered early in the work that *Sh. alkalescens* antiserum failed to agglutinate homologous organisms by the slide technic although it consistently agglutinated them through high titer when incubated in test tubes overnight. It was found that *Sh. alkalescens* contains a heat-labile component which prevents agglutination by the slide technic. This difficulty was overcome by boiling all *Sh. alkalescens* antigens for $\frac{1}{2}$ hour. Later it was discovered that the antigens for *Sh. alkalescens*, type II, *Sh. ceylonensis* and *Sh. madampensis* must be treated in the same manner. The practical problem had been solved, but the question of the relationship of this factor to others vital in understanding the antigenic structure of these organisms remains unanswered. If there are heat-labile components there may well be others which can be neutralized or inactivated by organic or inorganic substances to produce better sera.

The question of the validity of Flexner races X and Y as proposed by Andrewes and Inman arises frequently. According to Boyd, the Y strain exists only in the form of old laboratory strains which have lost the type-specific factors. Ten strains which appeared to be authentic Y types were received in July, 1945, from an outbreak of dysentery at Camp Wheeler, Georgia. These identifications were confirmed by other investigators. An antiserum was developed which subsequently agglutinated seven additional organisms in our unidentified collection. It seems probable that the Y group will have to be reinstated as a valid race although for the present it is considered only in experimental studies at the Army Medical School. A strong cross-reaction exists between the authentic Y types and the organism designated *Sh. rabaulensis*, by Barnes, Wheeler, and Dammin,¹⁰ a type isolated and established as an authentic species from clinical cases of dysentery in Rabaul.¹¹ Our isolates came from clinical cases in Puerto Rico. The Y agglutinins in *Sh. rabaulensis* antiserum cannot be completely absorbed and yet there is some evidence to indicate that they are separate and distinct entities.

The strong antigenic relationships between some strains of *Sh. sonnei* in the "rough" (phase II), the D-19 of Boyd, and the Q1030 of Sachs is an example of one of the questions that must be answered before the production of specific monovalent sera can be considered complete. Other similar problems require further investigation but it is felt that the preparation of absorbed monovalent sera represents a great advance. Many thousand strains of *Shigellae* and *Shigella*-like organisms have been received at the Army Medical School, and less than 50 remain unidentified when studied with these sera. These strains are being studied and it may be found possible to establish

some new serotypes within the genus.

It is felt that control of bacillary dysentery in the Army has been helped by the development of sera which enable one to make an etiologic diagnosis within 48 hours. This makes possible an early study of the epidemiology so that necessary steps can be taken early to eliminate sources of infection.

ACKNOWLEDGMENT—This program was initiated under the direction of Dr. C. V. Seastone and Dr. K. S. Wilcox.

Norton Medical Award Changed

The revised terms of the annual Norton Medical Award for book manuscripts written for the lay public by professional workers in the field of medicine have recently been announced by W. W. Norton & Co. There is now no final closing date for the submission of manuscripts and the Award is now not limited to any one year.

Instead of an outright cash grant of \$3,500, an award of \$5,000 is now offered as a guaranteed advance against royalties. Either complete manuscripts or detailed table of contents together with one hundred pages of manuscript may be submitted. Full details may be secured from W. W. Norton & Co. Inc., 101 Fifth Avenue, New York 3, N. Y.

The Common Rat as a Source of *Erysipelothrix rhusiopathiae*

CHARLES H. DRAKE, PH.D., AND ELIZABETH R. HALL, M.S.

*Department of Bacteriology and Public Health, Washington State College,
Pullman, Wash.*

THE rôle of the common rat (*Rattus norvegicus*) in the spread of disease is too well known to require further emphasis. However, it should be pointed out that the rat may be an easily overlooked source of some pathogenic organisms not usually associated with rodents.

The authors recently conducted a rat survey in a small section of southeastern Washington in an effort to determine whether the animals were carriers of *Leptospira icterohaemorrhagiae* and therefore a potential source of human cases of Weil's disease. Unfortunately, local circumstances brought a halt to the work after 85 rats had been examined by one or more of the following methods: kidney culture, kidney sections, animal transmission, agglutination tests, and dark-field examination of diluted ground kidney. As many as possible of the methods were used on each animal, but since the rats were collected by trapping and shooting, there were some cases in which blood was not available for agglutination tests and often the animals were not suitable for cultural examination. No evidence was found which indicated the presence of *Leptospira* in local rats but several interesting incidental observations were made.

Whenever possible a white Swiss mouse was injected with kidney, liver and spleen tissue from each rat. Tissue injections from two different rats caused death of the experimental mice within a

week and further transmission and cultural examination led to the isolation of *Salmonella enteritidis** from one and *Erysipelothrix rhusiopathiae* from the second animal. Neither of the source rats showed any gross lesions at autopsy and both appeared normal at the time of capture.

The strain of *E. rhusiopathiae* was identified by its morphology, cultural reactions, animal pathogenicity, and by agglutination and protective tests with commercial swine erysipelas antiserum.

Intraperitoneal injection of 0.1 ml. of a broth culture killed mice in 48 to 96 hours with characteristic symptoms, including conjunctivitis, and the organism was readily reisolated from the mice. The organisms were easily demonstrated by strained smears or by dark-field examination of blood from the mice 24 hours after infection.

Both slide and tube agglutination tests were set up with commercial swine erysipelas antiserum, and the culture was isolated from the rat. A control series consisting of a known strain of *E. rhusiopathiae* was tested against the serum at the same time. The organism from the rat gave a positive reaction at a dilution of 1-1,280 by both tests while the known strain gave a complete reaction only at a dilution of 1-640. The difference may be due to the fact that

* The authors would like to express appreciation for the assistance of Dr. P. R. Edwards of the Salmonella Typing Station, University of Kentucky, for confirming our identification of this organism.

the known strain, obtained through the courtesy of the Washington State College School of Veterinary Medicine, had been carried for many transfers on artificial media.

The same serum was also used for protection tests on mice. Fifteen white Swiss mice weighing 17–20 gm. were injected intraperitoneally with 0.2 ml. of a 72 hour proteose peptone broth culture of *E. rhusiopathiae* isolated from the rat. Five of the mice were used as controls and all died by the fourth day. Five of the mice received an intraperitoneal injection of 0.5 ml. of a 1–10 dilution of antiserum. This dosage was insufficient to protect the animals completely but delayed death 24 to 48 hours as compared with the controls. The remaining five mice received 0.5 ml. of undiluted antiserum intraperitoneally; one mouse died on the sixth day but the others remained well and yielded no *E. rhusiopathiae* when killed and cultured six weeks later.

The cultural reactions of *E. rhusiopathiae* have been rather variable in the hands of different workers, as pointed out by Karlson and Merchant.¹ However, most authors agree that in ordinary fermentation media, acid, but no gas, is formed from glucose and lactose but no change is observed in sucrose and mannitol. These properties were shown by the organism isolated from the rat. A small amount of hydrogen sulfide was produced on Treece's medium, which agrees with most observations. Packer² reported that a medium containing 1 in 1,000 sodium azide and 1 in 100,000 crystal violet in a blood-agar base at pH 6.8 inhibited all organisms tested except *E. rhusiopathiae*. A proteose peptone agar base adjusted to pH 6.8 and containing the above concentrations of sodium azide and crystal violet supported growth of our strain for five serial transfers. The growth was distinct but of lesser amount

than on the same medium without the inhibitory substances. We have found that *E. rhusiopathiae* will also grow on media containing 1 in 2,000 potassium tellurite; appearing as small, dark colored colonies.

DISCUSSION

E. rhusiopathiae has been isolated from a wide variety of mammals, birds, and fish. Human infections are not rare and at times appear to be an occupational hazard. In view of this, it seems strange that the only previously recorded isolation of *E. rhusiopathiae* from rats was made recently by Stiles.³ His observation differed from ours in that the infected rat was obviously diseased and partially disabled by the infection. This organism may be a more frequent parasite of rats than has been realized, and rodents may play an unrecognized rôle in its spread. In our case the evidence is insufficient to decide whether or not the rat was a healthy carrier or was in the prodromal stage of the disease at the time of capture. If this organism is more commonly associated with rats than has been recognized, it affords a possible explanation of the isolation of the bacterium from various materials in which a source of contamination has not been apparent. However, the growth of *E. rhusiopathiae* in the presence of substances inhibitory to most organisms (sodium azide, crystal violet, potassium tellurite) may be related to its apparent ability to survive for long periods in unfavorable materials.

SUMMARY

Erysipelothrix rhusiopathiae was isolated from an apparently normal rat captured during a leptospirosis survey. The organism was identified by animal pathogenicity, cultural reactions, agglutination tests, and by mouse protection tests with known antiserum. The ability of this organism to grow in the presence

of sufficient crystal violet and sodium azide to inhibit most other organisms has been confirmed. The organism was also found to grow in the presence of 1 in 2,000 potassium tellurite.

Attention is called to the possibility that rats may be an overlooked source of *E. rhusiopathiae* even though only one previous isolation has been reported from this animal. The present isolation differs from the one previously reported in that the animal showed no

symptoms or gross pathology of the disease although the possibility that it was in a prodromal stage of infection cannot be dismissed.

Need for Federal Research Grants To Study Environmental Sanitation Problems

The following resolution was adopted at the joint meeting of the Great Lakes Board of Public Health Engineers and Upper Mississippi River Boards of Public Health Engineers at a meeting on February 6, 1947:

WHEREAS, the growing importance of environmental sanitation in the field of public health is recognized, and

WHEREAS, there are a number of environmental sanitation problems requiring further research and study to effect practical solutions, and

WHEREAS, a program for fundamental research and study of environmental sanitation problems through research grants has already been inaugurated by the U. S. Public Health Service, and

WHEREAS, even though the activities of this

program have been thus far limited, its value has been demonstrated.

THEREFORE, the Upper Mississippi River Board of Public Health Engineers and the Great Lakes Board of Public Health Engineers in joint meeting assembled February 6, 1947, in Chicago

RESOLVE that the value of this fundamental research in environmental sanitation through research grants is recognized, and recommend to the U. S. Public Health Service that additional appropriation be requested of Congress for such grants.

The Boards of Public Health Engineers were established under the Great Lakes Drainage Basin Sanitation Agreement and the Upper Mississippi River Drainage Basin Sanitation Agreement.

Health Education in Mexico*

MANUEL GONZÁLEZ RIVERA, M.D.

*Chief, Division of Health Education, Ministry of Public Health and Welfare,
Mexico City, Mexico*

HEALTH Education in Mexico, as a governmental activity, was initiated on April 21, 1922, when the Section of Health Education and Propaganda was founded in the Public Health Department. From that time until 1940, health education activities were gradually increased and the Bureau of Health Education received increasing official recognitions, assuming successively the rank of "Section," "Office," "Department," and, in 1940, "General Direction."

Health education of the public has been accomplished by several means, such as by pamphlets, leaflets, posters, and other printed materials. Educational films began to be utilized and some endeavors were made to produce documental films. Talks and conferences given to school children, mothers, workmen, or unclassified groups, were numerous. Unfortunately this educational work was intensive only in and around Mexico City. In the rest of the country health propaganda was reduced to the meager distribution of a monthly publication and some printed materials, and to holding once a year a Week of Hygiene in the cities or towns in which there existed a Hygiene Center or Unit. At the beginning of the sexennium that we are going to review, the overall picture of health education only showed a more or less broad program in Mexico

City, and nothing important in the rest of the country.

Developments have occurred in two periods of time: from its beginning, in December, 1940, to October, 1943, when the Public Health Department and Ministry of Public Welfare were united to form the present Ministry of Public Health and Welfare. The second period includes three years, from October, 1943, to the present time.

In the first period the aims of health education were determined the educational work developed and was extended to the states and territories. Some attempts were made to introduce health education in the schools with the organization of school health committees integrated by the pupils, under the counsel and guidance of doctors and teachers.

At the beginning of the second period, when the Public Health Department and the Ministry of Welfare were blended to create the Ministry of Public Health and Welfare in 1943, noteworthy changes in the plans of health education took place. The Director of Health Education became a technical consultant for the services of public health in the whole country, through sections of health education founded in the capital of each of the states or territories.

In order to be able to put in execution the enlarged plans, the Division of Health Education has been divided into four sections, as follows:

1. Publicity and Propaganda

* Presented before the Public Health Education Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1946.

2. Health Education Guidance
3. Health Exhibits
4. Mail Courses -

The first section, Publicity and Propaganda, is considered as a laboratory in which we elaborate different materials that are sent to the local health services in every state or territory, where doctors, nurses, and other public health workers make use of them. For personal or direct propaganda by spoken word, conferences or talks are prepared and mailed to doctors and nurses who are at work in Hygiene Centers or Units. Copies of various scripts, sketches, dialogues, etc., are sent to all radio stations, as well as records with electrically transcribed programs. Twice a week, we transmit through "Radio Continental" (1030 kc.), programs carried out by groups of doctors, social workers, clerks, etc., of our staff. "Radio Gobernación" (1060 kc.) broadcasts a weekly program performed by the boys and girls of primary schools. Straight health talks are seldom used; we consider the above cited ways of broadcasting more suitable to the needs and idiosyncrasies of our common people.

We have just begun to engrave records with simple and easily interpreted lessons in hygiene which will be broadcast three times a week for the children of primary schools through a radio station recently acquired by the Ministry of Public Education. Also in this section, printed materials are produced to be distributed by health organizations in the country: pamphlets, leaflets, booklets, posters, etc., on the subjects of smallpox, malaria, tuberculosis, venereal diseases, diphtheria, typhoid fever, nutrition, child health, sanitation, etc.

We are writing and editing a monthly publication whose title is "Salud" (Health). Each issue is wholly devoted to a single subject in such a manner that every edition is like a simple and

easily read monograph on typhus, malaria, alcoholism, school hygiene, nutrition, eugenics, dental hygiene, housing, etc.

Other periodical publications of the Ministry of Public Health and Welfare are the quarterly review of the Institute of Public Health and Tropical Diseases, scientific review of the Institute, edited by the Division of Health Education, and the house organ "Salubridad y Asistencia" published every other month.

In 1944 we began to make an almanac with various ephemerides concerning the history of medicine and hygiene. Most important in this almanac are short and pointed phrases, documental or instructional, inserted in a daily sheet and inserted in such a way that the reader receives from the beginning to the end of the year, a short course in hygiene. The almanac for 1945 was dedicated to "General Hygiene and Preventive Medicine"; the one for the present year is especially devoted to mothers and teachers and is an elementary treatise on child health. The calendar for the forthcoming year has just been prepared and will instruct the readers about the prophylactic measures against the chief communicable diseases in our country.

We have not neglected the great importance of the press as our effective ally in the health education of the people. We have a catalogue of all newspapers or reviews in the country and we frequently write for them articles, editorials, health stories, short phrases, etc., which are published by them without charge.

We are doing our best to obtain the benefits of movies in health education. We have recently made attempts to produce 35 mm. films. The first was documentary, covering the production of smallpox vaccine and the immunization against this disease; another covered the subject of First Aid, and the

subject of the third was on the subject of milk as a food and the way in which the Ministry of Public Health and Welfare is preparing and providing ten thousand bottles of milk daily to the Child Health Centers and Child Keeperships for the indigent children of Mexico City. We have also made some 35 mm. "trailers" for the newsreels.

In the City of Mexico we have two corps of health educators and twenty-five in the rest of the country, who spread health education by several means, chiefly by showing of educational films. In these programs we use 16 mm. films and before each educational picture, we give a short talk related to the specific subject.

In September, 1946, with financial assistance from the Institute of Inter-American Affairs, we began to print some leaflets in offset, with colored figures reproduced from the educational films of Walt Disney, having in the reverse side the most important principles of health education and prophylactic measures recommended in the film. Therefore we are using in a single session and anent a single subject matter, three of the best methods of health education: the spoken word, motion picture, and attractive, pertinent printed materials.

The Institute of Inter-American Affairs has loaned 20 projectors to us and has supplied various films and 5 projectors for the States.

On June 15, 1944, the Children's Health Theater was inaugurated. We called it "children's" not only because of its adaptation to the mind of children, but also because it is performed by boys and girls of primary schools. Many a time we have realized the effectiveness of the dramatization as a way of giving health instruction, not only to the little players, but also to their school fellows, to their families, and even to the public in general.

In October, 1945, puppets began to

be utilized in health education, and it is our plan to use them largely in the forthcoming year, by means of the ambulant theater set up on a truck.

The Section of Health Education Guidance, plays a very important part in our program. It draws up the plans and subjects of health education to be executed by the local health services in the whole country. First of all, every local health service undertakes a preliminary survey to investigate the most important and urgent health education problems in the zone under its care. The results of the survey are reported to the Division of Health Education together with the information about procedures available in the locality, such as newspapers, radio, and motion pictures, the Parent-Teacher Association, health clubs or committees, etc. The Division of Health Education, with due regard to the data of the survey in every zone, develops the appropriate health education program and sends this to every health office.

It is a great misfortune that school hygiene in Mexico is not under the control of Ministry of Public Health. It is under the care of the Ministry of Public Education and only the public schools of the City of Mexico enjoy the benefits of the School Health Service. Consequently, we public health workers have been deprived of the possibility of contributing to health education in the schools. In response to our urgent pleas in 1944, the Division of Health Education arranged a meeting attended by many delegates both from the Ministry of Public Education and the Ministry of Public Health. In this meeting the foundation was laid for the collaboration of public health workers with teachers of primary and high schools under the control of Ministry of Public Education in the whole country, mainly in the rural areas.

Since then, the participation of public health workers in health activities

of the schools has constantly grown, both in extent and significance. Doctors and nurses of the health services in the whole country are visiting schools, giving health talks to pupils, teachers, and parents, creating or reorganizing parent-teacher associations, scholastic health committees, anti-alcoholic units, athletic clubs, etc. Except in Mexico City, doctors of public health services make the school medical examinations both for the pupils and the teachers, and in the most important towns dental clinics have been established in which school boys and girls receive special attention and care.

The Division of Health Education is paying great attention to health education for workers in factories and industries. In Mexico City there are two corps who visit the factories to give health talks to the workers, to convince and induce the employers to coöperate in the eradication of unhealthy conditions in the workshops, etc.

Another task of the Section of Health Education Guidance is to consult with doctors, nurses, or teachers about health education and to answer questions coming from lay people about preventive medicine or hygiene.

We have written and edited the first and second editions of a booklet about the communicable diseases in the rural areas specifically for teachers, to the end that they might learn the principal symptoms of the most frequent communicable diseases among the school children, and the prophylactic measures to be taken in order to prevent the spreading of disease. Formerly we printed and distributed an elementary manual of hygiene, compiled for rural teachers exclusively, to help their task in health instruction given to their pupils.

Finally, the Section of Health Education Guidance controls, advertisements in bearing upon fraudulent and quack

practices. In Mexico there are very few doctors who use professional advertisement and these are not accepted by the honest practitioners. According to law, professional advertisements concerning medical activities must be approved and registered in the Ministry of Public Health, and cannot be published without registration.

The Section of Health Exhibits includes, in the first place, the National Health Museum centrally located in Mexico City, with two store windows in which exhibits are changed at frequent intervals. The Health Museum, inaugurated with some exhibits acquired from the Cleveland Museum in 1942, is constantly increasing its stock by the manufacture of various exhibits, dioramas, wax models, maps, posters, transparencies, etc., on such subjects as tuberculosis, venereal diseases, intestinal parasitosis, nutrition, maternal and child health, industrial hygiene, etc. It receives about one thousand visitors daily, including groups from schools and colleges. In the assembly room of the Museum, a health talk is given and educational films are exhibited twice a day. At all times, one doctor and three social workers are in attendance. A nurse is employed in the immunization against smallpox or diphtheria at request. Fourteen years ago the Public Health Department began to give mail courses on hygiene to rural teachers. Since 1944, the Division of Health Education is giving correspondence courses for visiting nurses in rural areas, and during the present year we began to give mail courses for rural midwives. We are now preparing courses for sanitary inspectors to whom we shall give instruction by mail, next year.

Concisely described, these are the health education activities of each one of the sections of the Division of Health Education in the Department of Public Health and Welfare in Mexico.

An Evaluation of the Effectiveness of the Astoria Plan for Medical Service in Two New York City Elementary Schools*

ALFRED YANKAUER, JR., M.D.

*Department of Public Health and Preventive Medicine, Cornell University
Medical College, and the Bureau of Child Hygiene, New York City
Department of Health, New York, N. Y.*

SELECTIVE Service rejection and "defect" statistics in the two World Wars have caused expressions of opinion to the effect that "the health level of the American people has not improved to the same degree as mortality in recent years."¹ It has also been stated that these findings reveal "many neglected physical and mental inadequacies which could and should have been prevented and corrected in childhood."² Such statements reflect upon the educational and medical supervision which the child receives in school, and raise the question as to how these services could be improved.

In New York City the elementary school health services operate on the basis of recommendations made by the Astoria Demonstration Study.³ These recommendations, known as the Astoria plan, were adopted in the fall of 1940. They center around continuity of record keeping and a yearly conference of teacher and nurse in which the health status of each pupil is reviewed. Children with questionable health problems or problems which cannot be handled directly by the teacher or nurse are referred to the school physician for examination. Routine health examinations by the school physician are performed only on children entering

elementary school who have not been examined by an outside agency. Throughout the remainder of elementary school the child is examined by the school physician only if "selected" at a teacher-nurse conference.

Certain questions have arisen with respect to the operation of the Astoria plan in the light of Selective Service findings. Are there sick or handicapped children attending regular classes who have not received medical care or proper school placement simply because routine examinations have not been performed, and teacher or nurse is not sufficiently aware of disease symptoms or signs? If a careful initial examination is performed, can the system of teacher observation be trusted to bring to light children in need of care? What would be the value of additional routine examination by grade, with and without the presence of the parent at the examination?

Since the Astoria plan has operated for a period of six years, the health of children now in the sixth grade of New York schools should be some indication of the plan's effectiveness, provided a sufficiently large and representative sample were examined. Such an examination should also disclose snags in the operation of the plan itself and

point the way toward an answer to some of the questions raised in the preceding paragraphs.

MATERIAL

Two elementary schools in the Kips Bay-Yorkville health district were selected for study. The 100 acre area from which these schools draw their pupils presents some significant features. On the one hand, the physical environment and conditions of life are poor, and the economic status of the population is approximately 25 per cent below that of the city-wide average.⁴ On the other hand, a medical center, a health center, a settlement house, and a large dental clinic are located within the area, and two other large medical establishments are within short walking distance. Thus adequate free or low-cost health, medical, and dental services are easily accessible outside of the school. In addition, considerable mass health education has been carried on in this district, and it has served as a city-wide training center for school physicians.

There were 149 pupils in the sixth grade classes of these two schools, of whom 114 (58 boys and 56 girls) constitute the subjects of this study. All children were white, and the majority were of Czechoslovakian, German, or Italian ethnic background. Ages ranged from 11 to 13, the majority falling 6 months on either side of the 12th birthday. In 108 cases the mother was present at the interview, and in the remainder a responsible adult member of the family was present. Seventy-seven (68 per cent) of these children had been examined by the school physician on entry to elementary school. The remainder had been examined at that time by private physicians or hospital clinics, and the results incorporated into the school medical records.

Thirty-five of the 149 children in the two schools are not included in this survey. Of these, 23 were not

given appointments because they had entered the school system after 1941, or because of parental inability or unwillingness to attend the examination, and 12 were given appointments which were broken. The school medical records and teacher judgments of these 35 children did not differ from those of the rest of the group, and it is not felt that their exclusion is of significance.

In New York City schools special classes exist for children with pronounced defective vision and with orthopedic handicaps or cardiac disabilities which prevent their attending regular classes. In addition, Health Improvement Classes are maintained for children to whom the unmodified school regime might be detrimental for a variety of medical reasons. Since the children examined were all attending regular classes, it is obvious that the group is a selected one, and it can be assumed that major physical disabilities have been eliminated from it.

METHOD

The parent was interviewed in the presence of the child, every effort being made to elicit a spontaneous anamnesis. Health problems and attitudes, the effects of previous medical contacts, the nature of family life in the home, and of parent-child relationships during the interview were particularly sought. Material contained in the school medical records was utilized for questioning. Elements of a routine pediatric history which remained uncovered after all leads had been followed were then reviewed directly. The interview was followed by a complete physical examination of the child, which included the eye grounds. Approximately 40 minutes were devoted to the combined interview and examination.

Weights and heights, Snellen chart tests of visual acuity, and group 4-A audiometer tests for hearing loss were taken from teacher recordings on the

school medical records. Sahli hemoglobin determinations were performed on each child, and urines were tested for abnormalities of the sediment and the presence of sugar and albumin.

Positive findings reflecting the physical and mental health of the child were recorded. In cases of suspected physical disease, referrals were made for further diagnostic assistance. Direct review of clinic records, interview with attending physician, or written reports from outside sources were utilized in arriving at diagnostic decisions. An estimate of whether a "defect" could have been noted prior to the current examination was made on the basis of existing records and direct questioning of the parent.

When an entire class had been

examined, the teacher was consulted and asked to select children who seemed disturbed in personal and group relationships, and this information was incorporated into the findings.

It should be emphasized that the method used in obtaining data is considerably more exhaustive than the usual school health examination.

RESULTS

1. *Physical Health*

Results of medical appraisal expressed in terms of physical defects are tabulated in Table 1. It will be noted that the majority are minor in nature or receiving adequate medical care. Defective teeth and nutritional deficiencies were not individually evaluated because it was felt that they require methods

TABLE 1

Distribution of Physical Defects in 114 Sixth Grade School Children

<i>Physical Defect</i>	<i>Known to School</i>		<i>Unknown to School</i>	
	<i>Under Care</i>	<i>Not Under Care</i>	<i>Under Care</i>	<i>Not Under Care</i>
Visual: 44 (57%)				
Refractory error	34	5
Traumatic cataract	1
Heterophoria (\pm 20/30 vision)	2	2
Surgical: 9 (12%)				
Phimosis	4
Lipoma (8 cm. in diameter)	1
Epigastric hernia (symptomatic)	1
Paraumbilical hernia (symptomatic)	..	1
Inguinal hernia	1
Anomaly of scrotum (fusion to thigh)	1	..
Cardiac: 8 (10%)				
Congenital acyanotic H D	1
Possible H D	2	2
Potential H D	1	..	1	1
Orthopedic: 6 (8%)				
Pronated feet (asymptomatic)	2	3
Forearm contracture (post-trauma)	1
Allergic: 4 (5%)				
Asthma (mild)	2
Rhinitis (mild)	1	1
Miscellaneous: 6 (8%)				
Hearing loss (less than 20 db)	1	..
Pituitary dwarfism (?)	1
Petit mal (?)	1
Albuminuria (cause undetermined)	1
Anemia (Probably nutritional)	2
Totals: 77	47	6	5	19
Percentage totals: 100%	61%	8%	6%	25%

more accurate than those employed in this survey. However, all children examined had received some form of dental care; no gross dental neglect was evident; unqualified signs of nutritional deficiency or undernutrition were not observed. Body posture was not evaluated because of its non-specificity. However, no organic postural defects were observed, and symptoms ascribable to "poor posture" were not manifest. Minor skin diseases (pediculosis, epidermophytosis, acne, etc.) are not included in the tabulation.

It is estimated that 18 (75 per cent) of the 24 defects unknown to the school could have been brought to school or parental attention prior to the current examination if elements of the Astoria plan had functioned as intended: 13 at the time of initial examination and 5 at the time of teacher-nurse conference.

Parental resistance accounted for 2 of the 6 defects known to the school but not under care, and the remaining 4 were overlooked at the teacher-nurse conference.

Of the 19 defects unknown to the school and not under care, 15 (79 per cent) could have been discovered at the present time by physical examination alone. Parental presence was necessary for the detection of 1, and laboratory procedures for the detection of 3.

Vision—No child with corrected vision of 20/50 or worse in the better eye was observed in this group. Thirty-nine children (20 boys and 19 girls), an incidence of 34 per cent of the total group examined, had uncorrected vision of 20/40 or worse in one or both eyes. They were all fitted with glasses and (with the 5 exceptions noted in Table 1) had had their glasses checked within the past twelve months. There were 6 children with heterophoria and a vision of 20/30 or better in both eyes. Two of them were known to the school and under care. The remaining 4 were unknown and not under care; 2 of these 4

were thought to need care after an ophthalmologic work-up and are listed in the table.

Tonsils and Adenoids—No children were observed in whom tonsillectomy or adenoidectomy seemed to be indicated on the basis of frequent sore throats, otitis media, cervical adenitis, hearing impairment, or nasal obstruction. Tonsillectomy and adenoidectomy had been advised in 26 children (31 per cent of the group) on examination in the first grade 6 years previously. Only 14 of the 26 had been operated upon. No significant differences in general health and frequency of respiratory infections could be observed between the tonsillectomized and the non-tonsillectomized groups.

Heart—Only one case of definite organic heart disease was present in this group. This was a congenital acyanotic cardiac, Class 1-B,⁵ known to the school and under care. It is considered that this case would have been overlooked on routine physical examination since it presented no unusual signs. There was no child with a definite history of a rheumatic episode or signs of clear-cut heart disease. There were 16 children in whom the possibility of heart disease arose but in whom a diagnosis of organic disease could not be made. In 6 cases there was a history of rheumatic fever in parent or sibling but no evidence of disease in the subject. In 3 cases an apical or left sternal systolic murmur heard on examination was considered of no significance after a cardiologic work-up. The remaining 7 cases were classified as "possible" or "potential" heart disease, using criteria of the New York Heart Association,⁵ after cardiologic work-up, including fluoroscopy, had been performed.

Hemoglobin—The mean Sahli hemoglobin of the group was 13.3 gm., with a standard deviation from the mean of 0.3 gm. There were 8 children with

values of 12.0 gm. and 2 children with values of 11.0 gm. These 2 children had no symptoms or signs of anemia and appeared to be in good health. They were not of Mediterranean origin, and it is considered that their anemias were of nutritional origin.

Urinalysis — Only one significant urinary abnormality was found. This was a non-orthostatic albuminuria with a negative sediment. In spite of further work-up its etiology is still undetermined at the present time. There were 10 cases of orthostatic or benign albuminuria (an incidence of 9 per cent). Repeated clean-voided specimens were negative in the case of 4 girls who had shown 6 or more wbc/hpf. There were 2 children who had past histories of acute glomerular nephritis but showed no evidence of disease at the time of examination.

2. Mental Health

An impression of disturbing factors in the child's home environment and emotional life was sensed in 44 children (26 boys and 18 girls). This comprises 38 per cent of the total group. Thirty-three of these children showed some evidence of disturbance in their classroom work and associations as observed by the teacher. Of this group, 10 were considered so disturbed that formation of mature patterns of thought and a constructive approach to adult reality situations were seriously interfered with, and the probability of future psychosomatic problems correspondingly enhanced.

All of these 10 children were known to the school in the sense that their present and past teachers were aware of and had recorded their deviant behavior. However, its significance was not always appreciated by them. Five of the 10 children had been selected for examination by the school physician. Five had been taken frequently to purely medical agencies because of

somatic complaints, and one child had received intermittent psychiatric help through a social agency.

Brief protocols of 3 typical cases are presented to show how these impressions were gained.

Charles H., age 11½, is a moderately obese, quiet child whose father believes that he must stay out of fights and roughneck associations and "go his own way without making and trouble." Therefore he goes to the park with his mother after school hours and plays by himself. He has never been away from home nor will his mother consider sending him. She is certain that she will only have to take him home again as she did with his thin (enuretic until the age of 15) older brother who has recently been rejected by the Army because of "high blood pressure." During the examination the boy is abused by his mother because of an undershirt which is not spotless (yet by no means unclean), and he is praised for being such a neat, clean child who is always careful of his appearance. His obesity is easily accounted for by the quantity and quality of what he is reported to eat. Almost in the same breath he is derided for not adhering to a low-carbohydrate regime prescribed by a physician, yet reminded with pride how eager his mother is to fulfil his expressed food desires. He is practically badgered into saying that he has everything he wants. It is difficult to get him to talk in his mother's presence, but he expresses no overt desire to change his way of life. Yet he frowns and appears upset when his mother is talking, seeming particularly disturbed when she discusses his brother's camp experience. His teacher states that he is silent, shy, and studious in class, and always holds himself apart from the group. His mother accompanies him to and from school every day and he is regarded as something of a curious phenomenon by his classmates.

Eileen S., age 11 3/12, is a thin, hirsute, overactive child who has been taken to many clinics and private physicians by her stout, anxious mother because of her "poor appetite," "nervousness," vomiting, headaches, and a variety of other complaints. She has been studied thoroughly and hospitalized on two occasions. No appreciable benefit has resulted. Her mother states spontaneously that she has spoiled her child and probably that is the whole trouble, but this thought is something she tends to dismiss with a smile as unimportant. Eileen prefers to spend her spare time reading or helping around the house.

The reason she gives for not participating in extracurricular group activities is that she is "afraid of getting nits." Her teacher has observed that she finds it difficult to remain on friendly terms with other children in the class and frequently quarrels with them. She is a very conscientious, aggressive, and competitive scholar. She worries a great deal about the caliber and quality of her school work which is, in fact, quite superior.

Walter P., age 12 3/12, a thin, drooping child of a widowed mother, sucks his thumb and occasionally wets his bed. He has little contact with children his own age except in the classroom and seems to prefer the society of adults. His mother feels that he would only get beaten up by bigger and rougher boys and that this is a commendable preference anyway. He spends a great deal of time with paternal relatives where, as the only child, he is deluged with presents, compliments, and attention. On examination he is extremely tense and cannot be drawn to talk at all. He is quite embarrassed at having to disrobe. His teacher has noted that he is very unpopular with his classmates. He annoys and teases them but runs away in fright when he is attacked, frequently coming to her whining and crying over a quarrel he himself has instigated.

COMMENT

Remarkably little evidence of physical ill health was observed in the group of children examined. The majority of physical defects or adverse conditions found were known to the school and under care. Most of those not falling into this category could have been brought to parental attention earlier if a more complete initial school examination had been performed. The Astoria plan functioned satisfactorily in these two schools.

However, these observations are necessarily limited to the district in which the survey was made. Its characteristics have already been pointed out, and it is entirely possible that, in an area where medical facilities are less easily accessible, different conditions prevail among the school children. For this reason a similar study is contemplated in schools located in a dis-

trict whose socio-economic level is on a par with that of Kips Bay-Yorkville, but in which medical and health facilities outside of the school are not as adequate.

If viewed solely as a screening mechanism for the detection of physical defects, the presence of the parent at the current examination was unnecessary. However, such a conclusion is overbalanced by the demonstrated value of the parent's presence in obtaining further study and care for defects^{3,9} as well as by other factors which will be discussed.

Recent trends of thought in the field of school health^{7,10} have emphasized the fallibility of shaping school medical services solely to prevent and correct physical defects. The importance of educating parent and child to seek early medical assistance, of promoting a positive attitude toward the maintenance of health, and of dispelling inherent fears of doctors and disease by making the examination a desirable educational experience, has been stressed. The presence of the parent and the provision of adequate physician time are essential if this is to be accomplished in the elementary school.

Judging from the findings detailed in the section on mental health, the more time and care that is taken in the interview, the more psychic and behavior problems will be unearthed. Limitations of time and technic precluded a more accurate evaluation of the degree and significance of psychic disturbance in the individual child. Yet these findings as a whole are significant. They emphasize that this is a major field for study and direction in school health work. This is particularly true if psychic disturbances in childhood are viewed broadly as the generating forces in adult personality types and many forms of psychosomatic disorders, as well as of "mental disease" in a narrower sense.

In New York City the Bureau of Child Guidance of the Department of Education is set up to care for emotionally disturbed children and to work with teachers, and there are a number of hospital clinics and social agencies to which these children can be referred. Yet all these facilities are overburdened with work and able to reach only a small fraction of those needing their care. The necessity for expanding these facilities and for pediatricians and general practitioners to absorb some of their load is obvious.

For many years mental hygienists and some educators have felt that the adult and group contacts of the child in the classroom could be utilized to prevent a further ingraining of neurotic patterns of thought and perhaps to correct these patterns.⁶ Yet before such an approach can be realized, major changes in the school curriculum and administration, in the size of classes, and in the qualifications of teachers are called for.⁶ Public action effecting such changes should be vigorously supported by the medical and public health professions. They are part of a constructive answer to the challenge which the draft statistics presented, that of "seeking and correcting in childhood the roots of many adult diseases."⁸

SUMMARY

1. A health interview and examination of 114 sixth grade children is reported. The children attended two New York City elementary schools which have operated for 6 years under

the Astoria plan of school medical service.

2. Only minor uncared for physical defects were observed, but there were a significant number of children in whom the seeds of future mental disturbance were sensed.

3. Most of the uncared for physical defects could have been picked up if a more complete examination had been performed on entry to elementary school.

4. The Astoria plan of school health service functioned satisfactorily in the schools surveyed.

5. The need for further study and care of emotional disturbances among school children and some of the implications of this need have been discussed.

Rickettsialpox—A Newly Recognized Rickettsial Disease*

III. Epidemiology

MORRIS GREENBERG, M.D., OTTAVIO J. PELLITTERI, M.D.,
AND WILLIAM L. JELLISON

Acting Director, Bureau of Preventable Diseases, and Epidemiologist, New York City Department of Health; and Parasitologist, U. S. Public Health Service, Hamilton, Mont.

DURING the summer of 1946, an outbreak of an unclassified disease occurred in a housing development in one of the boroughs of New York City. A clinical, epidemiological, and laboratory study was undertaken by the New York City Department of Health in coöperation with the U. S. Public Health Service in July and was completed in October. This report will deal with the epidemiological features of the epidemic.

LOCATION OF OUTBREAK

The outbreak was localized to a development consisting of a group of 69 houses in the Borough of Queens in New York City, about 15 miles from the center of the city. The houses occupy three oblong blocks, each block consisting of 23 connected houses arranged so that some face wide courts and others face the street. They are three stories in height, two or three families living on each story, and each family occupying three or four rooms. The general arrangement of the houses is the same in each of the blocks. There are small houses in the immediate

vicinity, but no cases of the disease were reported in residents of these. The neighborhood is suburban in type with wide streets, many trees and bushes, well kept lawns, but surrounded at a distance by large lots of unkept grass, weeds, and scrub forest. Close to the development are several highways on which considerable traffic passes between New York and Long Island. A total of 483 families occupied the apartments in the development at the time of investigation. The total number of residents was about 2,000, of whom 600 were children under age 15.

Cases were first seen by physicians in the neighborhood at the beginning of the year 1946.† Some of the physicians thought they were dealing with atypical chickenpox; others were unable to make a diagnosis. By early summer it became evident that the disease was occurring in a sharply localized epidemic. Intensive investigation was started in July. Doctors practising in the vicinity were canvassed and histories were obtained of earlier cases. All newly reported cases were visited by one of us. Patients and other residents were

friends. A canvass was made of about half of the 69 buildings in the three block area and a systematic visit was made to each resident in these buildings.

Records of 124 cases who had become ill between January and October were obtained. These are arranged in Figure 1 according to week of onset. The sex distribution was approximately

equal: 63 males and 61 females were affected. Table 1 shows the distribution of cases by age. Cases occurred among all age groups, the youngest was an infant of 3 months, the oldest a woman of 71. The incidence in children under 15 was 5.3 per cent, in adults, 6.5 per cent. In the entire group it was 6.2 per cent. All residents of the buildings and most of the employees were white. There were, however, some Negro porters. No cases were seen among the Negroes.

CLINICAL FEATURES

The clinical features have already been described elsewhere.² In brief, there occurred an initial lesion at the presumed site of bite by a mite, a papule, which when fully developed measured 1/2 to 1 1/2 cm. in diameter. The papule became vesicular in the center and dried, leaving a black eschar. This eschar ultimately sloughed leaving a small scar. The regional lymph glands usually became enlarged. About

FIGURE 1

RICKETTSIALPOX - ONSET OF CASES BY WEEK - JANUARY TO OCTOBER 1946.

a week after the occurrence of the initial lesion, there was an acute onset of illness with fever, chills, sweats, backache, and headache, followed in from 2 to 4 days by a maculopapular and papulovesicular rash. The duration of illness from initial lesion to complete recovery was about 3 weeks; the duration of the acute symptoms and of the rash was about 1 week to 10 days. There were no complications and no deaths. Laboratory findings were generally negative except for leucopenia. The usual bacterial agglutination tests were uniformly negative in the convalescent as well as the acute stage of the disease.

EPIDEMIOLOGICAL FEATURES

There appeared to be no relationship between disease incidence and occupation. Many of the adult female cases were housewives. Cases also occurred among both men and women who worked in various occupations in different parts of the city. There were among them salesmen, manufacturers, office workers, teachers, foremen, etc. No one occupation predominated. The children of primary school age attended public schools in the vicinity; those of high school age travelled to one of several schools in the city.

The possibility that the disease was imported was investigated. Of the total number of 124 cases, 112 were born in this country. The remainder had been born in European countries but had lived in the United States for a number of years. The median length of residence in the same apartment was between 3 and 4 years. Only 3 patients had lived there less than 1 month. Except for a few whose cases will be discussed later, none had been out of the city in the month preceding the onset of illness. None of the cases occurred in returned veterans.

Although few of the patients manifested even mild gastrointestinal sym-

toms, the possibility of a source of infection through a common food article was investigated. Morning and evening meals were almost always eaten at home. Lunch was eaten at home by the housewives and the small children. The older children ate at the schools they attended and the employed adults ate in various restaurants near their places of employment. Provisions, including meats, groceries, and cakes, were purchased from one of several markets in the immediate vicinity. The same markets supplied families where cases occurred and those where no cases occurred. Furthermore, residents in the surrounding areas purchased their supplies from the same markets that were patronized by the residents of the development.

Milk was also obtained at the provision markets. It came in sealed glass or cardboard containers, pasteurized, and approved by the Department of Health. The milk was supplied to the markets by ten different wholesale distributors. The same brands of milk in similar containers were sold to other residents of the Borough.

Water was supplied to the development from the regular New York City system through six 3 inch brass service lines. All the piping was brass. Flush tubes of water closets were provided with vacuum breakers. All wash stands, bath tubs, and kitchen sinks were provided with over-rim water supply fixtures. Water pressure was adequate. No breakdowns, defects, or other emergencies had occurred for many months. Samples of water were taken at two different units; analysis indicated water of good, potable quality.

Sanitary inspections of the immediate neighborhood yielded negative results. Two vacant lots adjacent to the development were inspected. They were covered by vegetation. There had been heavy precipitation in the days prior to the inspection, but only one mosquito

breeding impoundment was found. This was in the basement of an unfinished building about 200 yards from the apartment houses. Mosquito larvae were abundant in this water, and numerous adults collected from the ceiling of the basement were identified as *Culex pipiens* L. by Dr. Alan Stone of the U. S. National Museum. Adults of this same species were found to be fairly abundant in dark basement corners in the affected apartment houses. Specimens collected in the apartment basements were tested for infection, with negative results. The shrubbery was carefully searched but no ticks were found. The lots were sanitary, and although dog droppings were seen and field mice were in evidence, no garbage or bulk of other offensive material was found. The seeded area and the shrubbery along the highways near the development were also inspected. Here, too, no insanitary conditions were found, nor were ticks observed in the shrubbery. The seeded areas in the immediate vicinity of the apartments were mowed regularly.

There were two dogs kennels near the development and these were inspected and their owners interviewed. The dogs were clean and free of fleas and ticks. The shrubbery at the kennels was likewise free of ticks. Two nearby riding stables, occasionally patronized by residents of the development, were also inspected. No mosquitoes were seen on the walls and ceilings and no ticks were found on the horses.

Although the management of the development did not permit animals in the apartments, some of the tenants did keep dogs. A number of these tenants were interviewed. None had noted ticks on the dogs. Examination of dogs seen near the houses did not reveal ticks or insects on any of them. In almost all instances the animals were quite clean.

The buildings were new and modern

in design. The apartments were generally found to be clean and spacious in relation to the size of the families concerned, and the standard of living was high. Most of the windows were screened. The tenants were specifically asked about the presence of insects. They rarely saw mosquitoes; flies were not bothersome; and ticks were never seen. All the tenants interviewed were certain, however, that rodents were abundant. These were house or field mice and were seen in the basements of the buildings, in the courtyards, and in some of the apartments. Mice were particularly in evidence in the basements, which were used as storage places, and which also housed the incinerators of the buildings. Living and dead mice were seen in the basements, in the incinerators, and in the courtyards, and mouse droppings were also in evidence.

The possibility that the rodents played a part in the transmission of the disease was considered and a temporary laboratory was established in one of the buildings in order to trap numbers of them for study, and also to examine them for ectoparasites. A clue to the possible vector was furnished late in July, 1946, by Charles Pomerantz, who discovered small mites on the basement walls. These were identified as *Allodermanyssus sanguineus* (Hirst).*

At this stage of our investigation a strain of rickettsia had been isolated from the blood of a patient.³ Antigens prepared from it (M K strain) gave positive complement-fixation reactions when tested with sera of recovered cases, but gave negative reactions when tested with the serum of normal human beings and of recovered cases of syphilis, endemic typhus, tsutsugamushi fever, and Q fever. There was some serologic relationship to Rocky Moun-

* Identification of original specimens was made by E. W. Baker, of the Bureau of Entomology and Plant Quarantine, U. S. Department of Agriculture.

tain spotted fever; about 80 per cent of the sera from recovered cases also gave a positive reaction with the antigen of Rocky Mountain spotted fever, but in lower dilutions than with the M K antigen. The name rickettsialpox was proposed for the disease. Later, an identical strain of rickettsia was isolated from the blood of another patient.

Systematic trapping of rodents and collection of mites from walls and mouse nests in the different buildings of the development were carried out. Several types of suction apparatus were used for drawing the mites into vials. While some of the mites were found on freshly trapped house mice (*Mus musculus*), most of them were recovered from the external walls of the incinerators in the basement. Some were flat and colorless and had apparently not recently fed, while others were engorged and bright red in color. Smears made from the latter showed typical mammalian erythrocytes. The numbers found varied in the different buildings. On the incinerator walls of some of the buildings no mites were found, on the walls of others they were found in small numbers, and on the walls of still other houses they were found in abundance, as many as 100 being collected from the walls of a single incinerator. It must be pointed out that differences in the temperature of the walls and other factors may have influenced the number of mites found at one time. No other rodents and no other rodent parasites were found in the development during our investigation. Rickettsial strains were isolated from each of two lots of mites. The isolation of these strains and the establishment of their identity with the M K strain isolated from a rickettsialpox patient were discussed in an earlier paper⁴ of this series and the name *Rickettsia akari* was proposed for the organism.

There was an incinerator in each building serving the needs of the six to

nine families living in the building—a total of 69 incinerators. Openings to a chute leading down to each incinerator were provided on the respective floors of each building; the openings were closed by a hinged, metal door when not in use. Each incinerator was located in the basement and was composed of two brick-lined compartments, the openings of which were protected by hinged iron doors. The upper and lower compartments were separated from each other by an iron grate. Both compartments were part of and continuous with the chute leading to the upper floors. Garbage, paper, and refuse thrown down the chute by the tenants landed on the fire grate of the incinerator in the basement. Once or twice daily an attendant was supposed to set fire to the material. As it burnt itself out, the ashes and small debris would fall through the grate into the lower compartment, whence it could be removed into large cans for disposal by the Department of Sanitation. All objects not reduced by fire were picked out of the upper compartment by the attendant. Even the debris falling through the coarse fire grate contained much food for mice.

This method of garbage and waste disposal might have worked out well under normal conditions. During the four or five years preceding the outbreak however, the services of laborers had been at a premium. In this group of houses, as elsewhere, the necessary complement of handymen was lacking; as a result the buildings were not cleaned as well as formerly; basements were dirty and cluttered up, and the incinerators were not regularly fired. Combustible material was not sufficient to complete incineration of the garbage. The accumulation of garbage in the upper compartments of the incinerators and even the debris in the lower compartment furnished an excellent food supply for mice. Both living and dead

mice were found by us on our inspections. When disturbed by the opening of the door to the compartment, the mice would scamper about and disappear in the crevices between the bricks.

Many of the tenants interviewed complained of the presence of mice. Some had seen them only in the basement, others complained in addition of hearing them at night in the walls. Some found mice in their apartments. In two instances, mice were actually found by the tenants in the beds used by patients. In one apartment, mouse droppings were observed in a patient's bed between the sheet and mattress, and mice were caught in traps laid in this apartment. Not all houses were equally afflicted nor were the three blocks of houses equally infested. Block I was apparently the greatest sufferer. Whether this was due to less adequate and conscientious janitorial service in this block compared to the others, we are not prepared to state. It should be mentioned that there was no regular exterminating service in the houses at the time of our investigation.

Complement-fixing antibodies of rickettsialpox were demonstrated in sera from trapped mice. Such antibodies could not be demonstrated in laboratory mice nor in mice trapped in the Washington area. An organism identical with the M K strain of rickettsialpox was recovered from one of the mice trapped in the infested apartments.⁵

A routine search for mites was made in the houses of the development, par-

ticular attention being paid to the basements and especially the incinerator walls. Some of the houses were visited more than once, but repeated visits were not made to all the houses. In 9 of the 69 houses no search was made because the basements were locked and the attendants could not be located at the time of visit. In Table 2, the total number of reported cases is arranged according to the block of residence and the presence of mites in the building. It will be noted that 67 cases were reported from 19 houses in which mites were found, an incidence of 3.5 cases per house, as compared with 42 cases observed in 41 houses where no mites were found, an incidence of one case per house. Stated differently, mites were found in 19 or approximately one-fourth of the houses; from these houses came 67, or more than half of the known cases. It is also interesting to observe that in each of two buildings in which mites were found in great abundance, one in Block I and the other in Block III, 8 cases were found as compared with an average of 3.5 cases per building in which mites were found, but not in abundance.

Another point of interest was the occurrence of multiple cases in families. The 124 cases investigated were reported from 78 families. Single cases were reported from 47 families, 2 cases each from 20, 3 cases each from 7, and 4 cases each from 4 families.

Although many of the patients referred to the initial lesion as an insect bite, none actually recalled being bitten

TABLE 2

Rickettsialpox Cases Distributed According to Residence and Presence of Mites in Building

Building →	Block I		Block II		Block III		Total	
	Number of		Number of		Number of		Number of	
	Buildings	Cases	Buildings	Cases	Buildings	Cases	Buildings	Cases
Mites found	12	47	3	4	4	16	19	67
No mites found	6	13	19	20	16	9	41	42
No search made	5	15	1	0	3	0	9	15
Total	23	75	23	24	23	25	69	124

and none saw a mite or insect at the site of the initial lesion. However, three housewives in whose families cases occurred had noticed tiny blood spots on the bed sheets.

After the investigation at the development was terminated, we examined two patients with rickettsialpox in other parts of the city, both of whom volunteered the information that they had been bitten. One was a boy of 17 who recalled being bitten on his arm while in a stable and scratching the site vigorously. The other was a nurse who said she was bitten on her right hand. Both later developed an initial lesion of rickettsialpox at the site of the bite, one on the same day and the other two days after being bitten. Neither had seen a mite or insect on the skin.

OTHER CASES IN NEW YORK CITY

As information about the clinical aspects of the cases began to reach physicians, we were called upon to see suspected cases in various parts of the city. By the time our investigation had ended we had seen 20 additional cases in four of the five city boroughs. Particular interest is attached to a group of cases in an apartment house in the Bronx at some distance from the site of the above outbreak and, as far as we were able to determine, completely unrelated to it. The house is an 11 story brick and stone building and has 102 apartments. There are two self-service elevators, and two incinerators. A physician,* who has his office in the building, informed us that he had seen many cases in residents of the building in the past few years, which he had diagnosed as atypical chickenpox. He had records of 10 cases. His description of the clinical findings was typical of our cases. Blood counts in all of his cases showed a moderate leucopenia, but other usual laboratory tests were

negative. We were able to interview two of the patients who had recently recovered and to obtain blood specimens from them. The sera gave positive complement-fixation reactions with the M K antigen (strain of rickettsialpox) in high dilutions; they did not agglutinate the antigens of *Proteus* OX 19, OX 2, or OX K.

The tenants and the physician stated that they were not bothered by mosquitoes, ticks, flies, or other insects, but mice had been seen. We visited the basement which is on a lower level than the main entrance. Many of the tenants use the basement entrance when leaving and returning. We inspected the incinerators and found garbage in the upper compartments. On the walls of one of the incinerators were many mites, both flat and engorged, which we collected. These were identified as *Allodermamysus sanguineus*. Three mice were trapped, one in the incinerator and two in the storage room. The serum of one of these gave a positive complement-fixation reaction with the M K antigen of rickettsialpox in a dilution of 1:64.

INCUBATION PERIOD

Since the patients had lived continuously in the development and since none recalled being bitten, the incubation period could not be definitely determined in most cases. In one instance, however, it was found to be 10 days. In this case a woman living in Manhattan visited her daughter and son-in-law, both of whom were ill, on one day only. She developed acute symptoms 10 days later; she observed an initial lesion 3 days before onset. In 2 cases outer limits could be determined: one of us (W.L.J.) became acutely ill 23 days after arriving at the development to set up a laboratory; an initial lesion was first noted 8 days before onset of illness. Another patient became ill 24 days after returning to her home from a vacation

* Dr. Victor Stern

she noted an initial lesion 9 days before onset of symptoms. In the case of two members of a family, the lower limit of incubation was determined. Both became ill out of town, one, 9 days after leaving home, and the other, 11 days; only one of them had observed a primary lesion 5 days before onset of symptoms.

CONTROL MEASURES

Methods of control are under study. The elimination of mouse harborages appears to be an important factor in such control. The landlord was ordered to clean up the basements, take adequate measures to kill mice in the buildings, and to see to it that the incinerators were properly fired at least once daily.

COMMENT

The results of the investigation of the epidemic in Queens indicated that we were dealing with a hitherto undescribed disease, rickettsialpox, caused by an organism, *R. akari*, which was recovered from the blood of two patients early in the disease. The concomitant finding of bloodsucking mites, *A. sanguineus*, in the group of buildings where the patients lived, and the recovery of *R. akari* from two pools of these mites justified the belief that the mites were the vectors of this disease. The only other parasites or hematophagus insects found in the buildings were adult mosquitoes. Several hundred were collected from dark basement corners. Some were tested for infection, with negative results. Specimens sent to the National Museum were identified as *Culex pipiens* L. by Dr. Alan Stone. The only rodents found in the housing development were house mice, which were present in large numbers. The finding of mites as ectoparasites of mice, the presence of mammalian erythrocytes in smears made from engorged mites, the laboratory determination of the presence of complement-fixing antibodies of rickettsialpox in the blood of trapped

mice, and the isolation of *R. akari* from one of them, indicated that the mice acted as the animal reservoirs. The occurrence of a significantly greater number of cases in buildings where mites were readily found and the finding of multiple cases in families strengthened the hypothesis that the mites were the vectors of the disease.

The initial lesion probably represents a reaction to the bite of an infected mite. That no patient remembered being bitten is not surprising in view of the small size of the mite and the fact that no itching or pain was caused. It is not unusual for persons to be bitten by ticks and to be unaware of the fact until the acarid is discovered adhering to the skin or scalp by another person.

It is interesting to observe that rickettsialpox, as here observed, is a domiciliary disease. In the epidemic described, incinerators played an important role in maintaining the infection. This was not due to anything inherent in incinerators but to the fact that if not fired frequently and regularly they become excellent harborages for mice due to the accumulation of garbage. Also, they are warm and the particular mites identified as vectors of rickettsialpox thrive well in warm places. However, cases of rickettsialpox may occur in homes where there is no incinerator service. We have observed several such in other parts of the city. In all instances, however, mice harborages existed.

The eradication of the disease where it exists and prevention of its spread depend on the eradication of mouse harborages. Where incinerators are used in a building, they should be fired frequently and thoroughly.

SUMMARY

The epidemiologic features of an outbreak of rickettsialpox in a housing development in New York City are discussed. Evidence is presented that the

disease is caused by *Rickettsia akari*; that it is transmitted by a rodent mite, *Allodermanyssus sanguineus*; and that the house mouse, *Mus musculus*, acts as a reservoir. The presence of mouse harborages in the basements was responsible for maintenance of the infection. Incinerators, especially since they were not fired nor cleaned frequently, served as sources of food for the mice and must be considered as a factor in the maintenance of the animal reservoir of the disease.

Award to Psychiatric Aide of the Year

The National Mental Health Foundation, in order to focus attention on the important rôle played by psychiatric attendants in the care of the mentally ill, to help gain prestige for those engaged in this work, and to encourage better standards of on-the-ward care, announces a \$500 award. This will be made in the fall of 1947 to the man or woman employed as a psychiatric aide or attendant in a mental hospital, who is judged to be worthy of the title "The Psychiatric Aide of the Year." The award will be based on skill, initiative, and imagination in the discharge of duties and kindness and devotion to patients under care. Additional cash awards of \$50 will be given to five nominees deemed worthy of honorable mention.

Nominations will be received from hospitals and one candidate may be nominated for every 1,500 patients on the basis of the July 1, 1947, census.

Neither nurses nor persons engaged in administrative duties may be candidates but only those now employed as psychiatric aides, attendants, charge attendants, or the equivalent and whose activities are directly connected with ward care of mentally ill patients.

The judges will be the following:

Albert Deutsch, author and journalist
Robert H. Felix, M.D., Chief of the Mental Hygiene Division, U. S. Public Health Service

June Joslyn, Executive Secretary, Oregon Mental Hygiene Society

Mrs. Ruth P. Kuehn, Dean, School of Nursing, University of Pittsburgh

Dr. Robert L. Sutherland, Director, Hogg Foundation for Mental Hygiene, University of Texas

Mary Jane Ward, author of *The Snake Pit*

All entries must be submitted before August 31, 1947. Entry blanks and further information may be secured from the National Mental Health Foundation, 1520 Race Street, Philadelphia 2, Pa.

Inactivation of Partially Purified Poliomyelitis Virus in Water by Chlorination. II*

SERGE G. LENSEN, PH.D., MORRIS RHIAN, M.S., AND
MAX R. STEBBINS

Bureau of Laboratories, Michigan Department of Health, Lansing, Mich.

THE authors reported in a previous paper¹ the results of their preliminary study on inactivation by chlorination of partially purified poliomyelitis virus (mouse adapted Lansing strain) in distilled water. Suspensions of 0.5 per cent and 0.25 per cent virus were used and the virucidal action of chlorine was tested after contact periods of 30 minutes, 1 hour, and 2 hours. The pH of the samples varied between 7 and 7.4. It was found that in samples with residuals consisting either of free chlorine or of mixtures of free and combined chlorine the virus was completely or nearly completely inactivated in less than 30 minutes. The results with samples in which there was only residual chloramine were not consistent.

The present paper is a report on our further work along the same lines, with the following differences: (1) Shorter contact period (10 minutes, 30 minutes, and 60 minutes) were used for samples with residuals consisting of free chlorine or free chlorine and chloramine, and longer contact periods (2, 3, and 4 hours) for samples with only residual chloramine. (2) The experiments described in the first part of this paper were carried out at the same pH range

as those reported previously, while experiments reported in the second part were carried out at a higher pH range (pH 8.95–9.25).

TECHNIQUE

Essentially the same technique was used as in our previous work. Therefore, only a very brief recapitulation of the technique is given here. The purification of the virus was carried out as follows: A 10 per cent suspension of mouse spinal cords and medullae in saline was centrifuged in an angle head centrifuge at 3,000 r.p.m. (instead of 1,900–2,000 r.p.m. in a horizontal centrifuge, as done previously) for 25 minutes, then ultracentrifuged at 20,000 r.p.m. for 15 minutes, and finally at 40,000 r.p.m. for 3 hours. The supernatant was discarded and the pellets were rinsed. They were then resuspended in saline and restored to the original volume. After a vigorous shaking in a mechanical shaker, the suspension was cleared by centrifugation at 4,000 r.p.m. for 15 minutes, and the supernatant used either for the experiments or for further purification. The sedimentation of the virus at 40,000 r.p.m. followed by resuspension of the pellet and clearing at 4,000 r.p.m. was considered as a cycle of ultracentrifugation. Where a higher degree of purification was desired, this cycle was repeated once or twice.

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946.

For the chlorination experiments, 100 ml. samples of water were used and the residual chlorine values determined by the orthotolidine arsenite test. For the experiments at the higher pH range a diluted sodium hydroxide-boric acid buffer was used. The temperature of the samples varied between 20 and 30° C. They were tested for virus content by intracerebral inoculation into white mice (0.03 ml.).

EXPERIMENTAL

A. Chlorination experiments at pH 6.85-7.4

The experiments carried out on the basis of contact periods of 10, 30, and 60 minutes are summarized in Table 1. A 0.5 per cent virus preparation purified by 1 cycle of ultracentrifugation was used for the experiments of March 14 and 15, 1946. In one sample, the residual after 10 minutes contact consisted of 0.5-0.75 p.p.m. chloramine with no free chlorine. There was only partial inactivation of the virus after 10 and after 30 minutes, and some virus could even be detected after 1 hour contact. The residuals in the other samples consisted, after 10 minutes, of mixtures of free and combined chlorine, the lowest value being slightly more than 0.15 p.p.m. free chlorine and slightly less than 0.45 p.p.m. chloramine. In all these samples there was no detectable virus after a contact of 10 minutes.

In the experiment of March 21, 1946, carried out with 0.5 per cent virus purified by 2 cycles of ultracentrifugation, there were only traces of chloramine and 0.75 p.p.m. free chlorine in one sample and slightly less than 1.0 p.p.m. free chlorine in the other. In both cases the virus was inactivated in less than 10 minutes.

Twenty-five hundredths per cent purified virus (1, 2 and 3 cycles of ultracentrifugation) was used for the experiments of March 28, April 4 and 12 and May 10, 1946. In the samples with residuals

containing free chlorine and chloramine, the virus was inactivated in less than 10 minutes. Even in the sample with 0.05 p.p.m. residual free chlorine and slightly more than 0.45 p.p.m. residual chloramine none of the mice injected after 10 and after 30 minutes contact became paralyzed (however, 1 mouse out of those injected after 1 hour developed paralysis).

In the experiments of April 12 and May 10, 1946, there were 3 samples with residuals consisting, after 10 minutes contact, of 0.4-0.5 p.p.m., 0.4 p.p.m. and 0.3 p.p.m. chloramine, respectively, with no free chlorine. In the first two samples there was complete inactivation of the virus in less than 10 minutes. In the third sample (with 0.3 p.p.m. residual chloramine) there was only partial inactivation of the virus even after 1 hour contact.

Another series of experiments was carried out with samples which contained, after 10 minutes contact, residual chloramine and no free chlorine. The samples were tested for virus content after contact periods of 2, 3, and 4 hours. As can be seen in Table 2, there was complete or almost complete inactivation of the virus in less than 2 hours by residuals consisting, after 10 minutes contact, of 0.75, slightly more than 0.4, 0.3-0.4, and 0.3 p.p.m. chloramine (experiments of April 18, May 15, June 13, June 7, 1946). In the other experiments there was either partial inactivation of the virus, or with residuals as low as 0.15-0.20 p.p.m. chloramine, no significant inactivation even after a contact of 4 hours.

B. Chlorination experiments at pH 8.95-9.25

Tables 3 and 4 give an account of the experiments carried out at a pH range between 8.95 and 9.25. The outcome of the experiments with samples in which the residuals consisted of free and combined chlorine and in which the virus content was tested after

free chlorine and chloramine should not be excluded. This is not in accord with the interpretation of Ridenour and Ingols who, in a recent paper,² seem to attribute the entire virucidal action of such mixed residuals to free chlorine, disregarding the possible virucidal action of chloramine.

In all our experiments carried out at a pH range between 6.85 and 7.4, with residuals consisting of free chlorine and chloramine, the virus in the partially purified suspensions was inactivated in less than 10 minutes. The outcome of the experiments at a higher pH range (pH 8.95–9.25) was different. In some of these experiments there was a complete inactivation of the virus in less than 10 minutes, while in other experiments there was only partial inactivation or no inactivation at all with residuals like 0.1 p.p.m. free chlorine and 0.4 p.p.m. chloramine, or 0.1 p.p.m. free chlorine and 0.65 p.p.m. chloramine (see Table 3). This seems to be in agreement with the findings of Mallmann,³ Rudolph and Levine,⁴ and others concerning the decrease of the bactericidal action of chlorine with the increasing pH. On the other hand, the outcome of the experiments with residual chloramine and no free chlorine (Tables 2 and 4) did not reveal a significant difference depending on the pH.

SUMMARY AND CONCLUSIONS

The inactivation of partially purified poliomyelitis virus (mouse adapted

Lansing strain) in water by chlorination has been studied at two different pH ranges. It was found that, at the pH range from 6.85 to 7.4, the virus was inactivated after a contact period of 10 minutes in all samples with residuals consisting of free chlorine and chloramine (even with as little as 0.05 p.p.m. free chlorine). At a higher pH range (pH 8.95–9.25), the outcome of the experiments with such mixed residuals suggests a decrease of the virucidal action of chlorine with the increasing pH: in some of these experiments the virus was not inactivated after 30 minutes or 1 hour in spite of the presence of residual free chlorine. In samples with residual chloramine and no free chlorine, no significant difference in the virucidal action was found depending on the pH. In spite of a certain inconsistency, the results of these experiments indicate that residual chloramine values of 0.5–0.75 p.p.m. usually inactivate the virus in less than 2 hours, while residual chloramine values of 0.2 p.p.m. or less fail to inactivate the virus.

Community Education in Hawaii Through Health Surveys*

RAYMOND GEORGE NEBELUNG, DR.P.H.

*Executive Director, Public Health Committee, Chamber of Commerce of
Honolulu, Honolulu, T.H.*

MOBILIZING community support for the conduct of our varied health programs constitutes one of the major issues with which we are confronted today. One of our greatest obstacles lies within our own ranks when we find both official and voluntary agencies competing with one another, often working at cross purposes, and vying for public recognition. Too frequently we become so engrossed with our own work that we are apt to lose sight of its relationship to the overall community health needs. This is to be expected inasmuch as all our energies in many cases are centered upon a particular problem. Consequently, not infrequently many of our more important but less spectacular problems receive little consideration, while those with a strong emotional appeal get more attention than they deserve.

If we are to continue to have public support in the way of increased appropriations we must begin to stress and focus attention on these issues. We must also secure more lay participation in the planning and conduct of our activities. Only through such coördinated effort can we hope to eliminate confusion in the public mind as to what problems should be given priority. Our education programs should be so con-

ducted that all our energies and funds are spent in a judicious manner. There can be no dispute over the need to arouse in the individual an interest in the maintenance of his own personal health as well as that of his community.

One of the most unexploited segments of our population is that of business. Here neither the official nor the voluntary agency has made a sustained effort to utilize either its personnel or its resources. Many business organizations on their own initiative have set up elaborate health programs for employees because they recognize the economic and social values to be derived from these services. More recently we find chambers of commerce establishing permanent health committees and taking an active part in support of our varied programs. With proper leadership, this group can become a potent force for improving the health of our people. Our job is to see that they are properly informed and that their energies are directed into the right channels.

The Chamber of Commerce of Honolulu is offering practical and professional leadership in support of health work in the Territory of Hawaii. The history of its activity dates back to 1900 when the business community first took an active part in a serious outbreak of plague in the city. Throughout its long history the Chamber's Public Health Committee has sponsored numerous new projects and has given active assistance to both

* Presented before the Public Health Education Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1946.

official and voluntary health agencies. Some of the projects which it has initiated and financed include rat and mosquito control activities, public health nursing, mental hygiene, and a school health workshop. It has also sponsored periodic surveys directed by prominent mainland specialists in the fields of community health, mental hygiene, tuberculosis, and sanitation. Committee members have likewise participated actively, and in numerous instances assumed leadership in these projects.

The Public Health Committee consists of 21 members appointed by the board of directors upon the recommendation of the committee chairman. Monthly meetings are held to discuss current problems, to review staff activities, and to study the progress of standing committees. The committee is assisted by an advisory group of five persons consisting of representatives from medicine and welfare organizations, supplemented by members of its own group. The function of this group is to review proposed new projects that are submitted to the committee for financial support.

The committee has long recognized that a high standard of community health is an important economic asset. It also recognizes that public health today has become big business with many ramifications, which not only embraces prevention of disease but involves care of the sick. Therefore it was not unusual when the Chamber, in August, 1944, organized a community health survey consisting of 17 committees with 34 subcommittees. More than 275 men and women representing business, the clergy, education, professions, and welfare organizations were enlisted in this undertaking. The objectives were to review and outline existing health problems, community resources and services, and on the basis of findings, to make recommendations for the expansion of services and to inaugurate new programs to meet

the unmet needs. The project was originally set up as a part of the Chamber's overall post-war planning study, with the president of the Territorial Board of Health as chairman.

It soon became evident that the direction of such a comprehensive undertaking would require full-time personnel. The Public Health Committee which was already engrossed in the hospital phase of the survey finally decided to recommend to the board of directors that a paid staff be employed to assist with its own activities and to direct the survey. This was done and a staff of trained public health personnel consisting of an executive director, health educator, research statistician, executive secretary, and clerical assistant was provided in February, 1945. Following employment of a staff all post-war health studies were transferred to the Public Health Committee.

A steering group was appointed to review progress of the various committees and to approve final reports prior to their publication. The president of the Territorial Board of Health serves as chairman of the group, which is augmented by one representative each from medicine, welfare, and the executive director of the Public Health Committee staff. The latter serves as liaison and consultant to the various study committees. Weekly meetings are held to review progress and to make suggestions to the liaison representative in order to facilitate and guide the course of studies. A mimeographed form is used to insure uniformity in making outline reports of progress.

Approximately six months were spent in organizing and outlining the studies of the different committees. In most cases the members of these committees are leaders in their respective fields. A regular schedule of meetings is followed until completion of their assignments. Data collected by designated persons with the aid of the staff are assembled

on progress forms by the latter and circularized to the other members. The material, which includes information regarding legal status, facilities, personnel, and programs, is then used as a basis for discussion in committee meetings. After the collection and compilation of data has been completed, committee recommendations are made in terms of immediate and long-range needs. A tentative final report in outline form is then submitted to the steering committee for review. The study committee chairman meets with this group which advises, offers suggestions regarding changes, and finally refers the report back to its committee for further consideration. The final revision is submitted again to the steering group for approval both in outline and narrative form. The purpose of the outline is to enable anyone readily to appraise the status of a particular service along with recommendations of the study committee without having to peruse the entire report.

Reports are issued as the work of the particular committee preparing them. Individual recommendations are considered to represent the views of the committee as a whole. Any dissenting opinions are likewise published upon request of a committee member.

The following studies have now been published: *Healthful Housing for the Territory of Hawaii*, *Public Health Organization and Administration for the Territorial Board of Health*, *Hawaii's Sanitation Problems* and school health programs. Remaining reports will be completed by the end of 1947.

Educational implications emanating from the survey have been very significant. Through joint planning we have achieved a more sound basis for improved working relationships among all groups. Likewise the association with persons of diverse education and experience backgrounds has enlarged the outlook of many. Be-

sides, it has developed in them a greater sensitivity toward resolving our health problems, and also has revealed many inherent weaknesses in our present health services.

Realizing that much of the survey value as a health education medium would be nullified unless an organization were established to bring into effective working relationships all the different forces and services that concern health, the Chamber of Commerce Public Health Committee again took the initiative and in September, 1945, organized the Oahu Health Council. Valuable information concerning community resources and local problems is now being made available, defining unmet needs along with plans for new programs. Therefore the next logical step was to focus public attention on these needs through a sustained and coördinated program of education in which all parties concerned might have an opportunity to participate.

The organization pattern is similar to that of councils which operate in mainland cities, with one exception, namely, that the executive director of the Public Health Committee serves as its permanent secretary. He and his staff are charged with the responsibility of carrying out the Council's mandates. The health educator on the staff devotes full time to Council affairs. Emphasis is placed upon group planning under professional direction with volunteer lay participation. Fifty-two organizations presently hold membership in the Council.

Prior to and after publication of a post-war health study, periodic digests appear in the press. These reports are then referred to the Community Education Committee of the Oahu Health Council whose function it is to motivate the community to put into effect the recommendations of the study committees. All types of educational media are utilized, including press

releases, radio, group discussion, and a monthly bulletin.

Specific accomplishments resulting from the combined activities of the health survey and the Oahu Health Council include adoption of the administrative reorganization plan proposed for the Territorial Board of Health which has already been augmented by additional services and personnel; inauguration of a school health workshop at the University of Hawaii; and sponsorship of a tuberculosis "field day."

The health survey is providing us with a blueprint that can be used for some years to come by all agencies in

the development of their programs. In the Oahu Health Council we now have the necessary machinery to supply to the public information on all health work in the community, a means of keeping survey reports alive, and a coördinating center dedicated to group planning.

Hawaii's overall health record today compares very favorably with that of most states. Fortified with these new instruments, we look forward to a time in the not too distant future when the Territory will occupy an enviable position in all phases of health promotion.

Regionalism as a Tool for Research and Social Engineering*

JOHN E. IVEY, JR., PH.D.

*Division of Research Interpretation, Institute for Research in Social Science,
University of North Carolina, Chapel Hill, N. C.*

REGIONALISM is an elusive idea. It appears as part and parcel of a variety of modern action and research programs and literature. The geologist, geographer, ecologist, political scientist, sociologist, public administrator, economist, and psychologist, to mention a few professions, all have found the regional concept useful. It seems to be everywhere at once, and therefore confounds attempts to nail the idea down for systematic study, description, and evaluation.

Why should the region, as a concept, be so generally used? For one reason, the region is a geographic concept which sets off one or several characteristics of the particular area with which the investigator is concerned. As the natural and social sciences have become more concerned with describing the spatial aspects of the phenomena with which they deal, the method of delimiting the distinguishing phenomena within regional boundaries has become more popular. In this manner, regional areas with differing, as well as similar, characteristics can be identified, contrasted, and compared.

It is obvious that there can be as many different types of regions as there are special characteristics of the environment being investigated. To put it another way, there can be as many

different regions as there are different purposes for delimiting them. Here we have the idea of the region in its most diffused manifestation: an area delimited on the basis of the homogeneity of one factor or aspect of environment. In this type of regional study the major focus is in finding the patterns which characterize the geographic occurrence of the particular phenomena being studied. From the scientist's viewpoint there are two general types of characteristics which are considered in delimiting these areas.

First, there are the phenomena of the natural environment: for example, water and land masses, topography, soil types, atmospheric pressure, temperature, humidity, rainfall, plant and wild life habitats, mineral belts. Second, there are the phenomena of the human social environment: for example, agricultural plant and animal habitats, demographic factors, mining, industry; factors of social organization, such as institutions, cultural values and attitudes, trade, and administrative factors.

In contrast to the single factor region, there is the composite region: an area delimited on the basis of homogeneity or similarity of a large number of factors. Composite regions are of two general types: natural regions and human use regions. The various natural and human social factors mentioned above, when related in these two categories, reflect composite patterns of environmental characteristics.

* Presented before the Health Education Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946.

time and in the place so described. In regionalism, however, we are interested in the life processes in motion within areas. Our mode of thought now must be changed from the snapshot to the equivalent of the motion picture.

Regionalism, as a science, is concerned with the measurement of existing environmental capacity, and with the social engineering of potential engineering of potential environmental capacity.

It is held that the scientific delineation of composite human use regions identifies areas within which there is the greatest possible *unity of operation* among the natural and social factors present. The capacity of the regions, so delimited, is dependent upon the quality and quantity of the life-sustaining materials and forces in the area.

THE REGION AS A UNIFIED BEHAVIOR SYSTEM

To measure the existing and potential capacity of a region, the scientists have to deal with two major behavior systems: the materials and forces of nature, and the social materials and forces. Man is included as a factor in both systems.⁴

The Materials and Forces of Nature

Every life supporting area of the earth has a measurable capacity for the production and maintenance of plants and animals. The ecologists tell us that these areas possess a community of plant and animal life which exists in a dynamic system. The sun, land, and water provide the medium. The process of photosynthesis, the hydrologic cycle, the food chains, the processes of invasion, competition, succession, and climax growth, are all a part of the reproductive and decay cycles of these areas.

As long as these areas are left undisturbed by man, they tend to reach a biologic balance. This is a state where the various living bodies of the environ-

ment remain in a system which maintains a productive equilibrium of living organisms in their relationship to one another, and to the sun, water, and land.

Natural environment thus is an energy system. Solar energy is trapped by plants which in turn draw inorganic elements from the soil and make them available in digestible form for the animal life. The plant and animal life represent the current *flow* of organic energy. Water force in streams and rivers represents the current *flow* of potential inorganic energy. The remains of past generations of plant and animal life have become, through ages of geologic processes, our *store* of organic energy in the form of coal, oil, and their related substances.

Each natural environment has a tempo, or rate of time, in which the reproductive process—the growth to maturity, and finally the death and decay of its living bodies—takes place. The tempo of the natural environment is geared to the life cycles of plants and animals, to the requirements of living organisms reacting to the inexorable forces of the climate and seasons. It is, therefore, a tempo largely geared to biological processes taking place in nature's medium of sun, water, and land.

These factors, and many others, are areas of investigation into which our biologist, botanist, zoölogist, plant and animal ecologist, chemist, geographer, and many other physical scientists must blend their judgments. For only through achieving an understanding of the unified behavior system of the natural environment can man build a permanent system of human social life.

The Materials and Forces of Society

Primitive man, with his simple wants, and his crude technology of fire and stone, fitted rather harmoniously into the biological equilibrium of the life

supporting areas where he settled. Modern man, with his complex wants, his glittering gadget civilization, and his work-monsters of fire and metal, can almost overnight destroy the biological equilibrium of nearly any environment he chooses to invade.

Men have created systems of social organization to furnish the necessary materials and experiences to meet their wants. The pattern of wants possessed by social groups directs their use of technology in fabricating and consuming the gifts of nature. Human wants are the caps, so to speak, which fire the processes of individual and group action. These multitudes of action patterns operate in systems of social values and attitudes which serve as guiding or controlling forces to give group life order and direction. These action patterns are further crystallized and thus shaped and driven, through such institutional systems as government, business, religion, family, and education.

The systems of group life, unlike the systems of the natural environment, are not set primarily to a biological tempo of reaction. By virtue of man's longer life span, his greater mobility in time and space, reasoning, language, and other such factors, social systems have a tempo of activity geared primarily to psychological factors set within a cultural framework.

The social environment can also be viewed as an energy system. The intensity of individual wants, the degree to which they find satisfaction and expression through group channels, the methods for and frequency of group action, the restraining or facilitating effect of group attitudes and values, the degree of group consensus on objectives and methods—all of these things condition the nature, force, and tempo of group activity. They affect the flow of biological and psychological energy of each individual into the social energy of group action. The existing capacity

of the social environment to meet human wants can be measured in terms of the resulting quality of health, personal and social adjustment of individual and groups, level of income, level of education, and other such factors.

In broadening the scope of group life, man has wrought great and important changes in the natural environment. In many areas he has partially replaced nature's system of plants and animals with those of his own choice. His methods of agriculture and industry have begun to strain severely, and frequently upset, nature's productive balance. The land is stripped of its cover and exposed to the fury of winds and rain. Wild life habitats are thus destroyed. Erosion fills the streams and rivers with silt, the air with dust. In such cases, the tempo of the social system has far exceeded the tempo of the available energy systems in the natural environment. The energy demands of society have exceeded the available energy supply of nature.

But in spite of his powerful and fast-moving civilization, man remains basically a creature of biology. As such, his rate of reproduction, span of life, and final appointment with death fit rather neatly into systems of prediction. His fertility, health, longevity, and cause of death are woven into a reciprocal relationship with his mode of work, concentration of numbers, level of education, level of economic achievement, and other similar factors.

Man: The Connecting Link Between Nature and Society

Each individual is thus a power center, or energy system. Through his behavior, the process of energy expression, he weaves his own purpose and ability into the social systems and into the forces and materials of nature. The energy system of the natural environment and the energy system of the social environment are related to one an-

other by the procedures through which individuals and groups channel the expenditure of human energy.

These systems of social behavior are becoming more and more susceptible to measurement, description, analysis, and guidance as the tools of the social scientist become more precise. The physiologist, neurologist, psychiatrist, psychologist, sociologist, anthropologist, economist, political scientist, educator, and public administrator here find fields of investigation which require a synthesis of judgment.

Thus within each composite human use region, there are two behavior systems in operations as one unit: the forces and materials of nature and the forces and materials of society. The capacity of each is, in part, a function of the degree to which they complement one another. Total regional or environmental capacity, in final analysis, is determined by how effectively the social system is organized to facilitate the maximum expression of human energy on the one hand, and to develop and sustain the energy producing capacity of the natural environment on the other hand.

At this point it should be clear that the process of measuring the productive capacity of a region requires methods of team research. To evolve an accurate picture of the reciprocal relationship between the complex systems operating in the natural and social environments, experts in natural and social science must be called on to *unify* or *synthesize* their judgments. Regionalism as a science of social engineering can be no more accurate and effective than the unity of theory, and the measurement of environmental capacity from which it proceeds.

DEVELOPING REGIONAL CAPACITY

Given certain soil types, climate, topography, minerals and wild life, what kinds of human use activities will

achieve the highest quality of sustained productivity of a particular region? In the same area, given the existing state of economic and social organization, the pattern of human wants, the social values and attitudes of the people, what educational and administrative methods will help the people to secure and sustain a higher level of living?

These questions represent the propositions which have to be translated into social objectives, social policy, administrative machinery, and action programs if the environmental capacity of an area is to be realized. It is at this point that regionalism, as a science for measuring environmental capacity, must call upon regionalism as a science of social engineering.⁵

Man is the link between the materials and forces of nature and the materials and forces of society. He is at once a creature of biology and culture, but also is a creator and transmitter of social systems. His manner of behavior as a force in society is for all practical purposes *acquired* or learned. In this sense, given an adequate natural environment, the quality of life that a region supports reflects the quality of scientific information and social values transmitted to and expressed by its inhabitants.

The bedrock of any society is the quality of nature's forces and materials, and the physical and mental health of the people. But the flow of human energy into productive and satisfying channels of expression is dependent upon how the social system is organized.

The scientific objective of social engineering is twofold. It aims to invent and assist in setting into motion systems of group activity which (1) gear the energy demands of the social system to the energy supply of the forces and materials of nature; and (2) achieve maximum development and expression of individual energies in satisfying and socially productive pursuits. Group processes and organization are media for facilitat-

ing the social expression of individual wants. The power or importance of group activity depends on the general level of acquired individual competence and degree of individual participation in social action.

Social engineering, then, is concerned with methods for facilitating the most effective outflow of individual energies into group expression. It must likewise master methods for facilitating the individual and social intake of scientific information necessary to guide individual and group activity into higher levels of welfare.

Regionalism, as a science of social engineering rests on the premise that new democratic systems of group activity within an area must spring from decisions of and action by the people. These new democratic systems must be rooted within, and be built out of existing patterns of group association and leadership. For only in this way can there be effected any organic and lasting change in a region.

Social engineering has three phases: planning, organization, and administration. Within a composite group-of-states region, these three phases are essentially educational processes.

The Planning Process

In planning, there are matters of design and layout of human occupancy patterns in the region, farm layout and management, water control and utilization, transportation and communication systems, layout of small communities and larger metropolitan areas into trade, manufacturing, residential, and recreational centers.

A basic part of the design pattern, however, is the pattern of social objectives which individuals and social groups decide upon. What kind of agriculture, what kind of industry, what kind of educational, health, and security services exist? What kind of government, what kind of business system are pres-

ent? The answers to these questions define a pattern of group wants which in turn shape the selection of alternatives for design and use of nature's materials and forces.

Obviously, such group decisions do not spring clear and loud from one gigantic public debate. They must evolve, sometimes slowly, sometimes rapidly, but always out of organizations and social systems of the area to be developed. To the extent that group decisions are based upon the results of regional research, the gearing of social systems with systems of nature will be closer. At this point, planning begins to blend with organization and administration.

Since the 1930's there have been in the United States at one time or another, as many as forty-five state planning boards. With few exceptions, these boards have worked as research organizations, having little or no functional relationship to the administrative agencies of state government. They have recommended plans but the process of bridging the gap between plans and social action has been, according to heads of thirty-five state planning boards, rarely achieved successfully.⁶

There is considerable evidence that the key to this failure rests in the abstraction of the so-called planning process from the process of state administration. A similar conclusion as to the cause for the failure of many city planning boards has been advanced by Robert C. Walker in his study, *The Planning Function in Urban Government*.⁷

In this connection, it is significant that the Tennessee Valley Authority, the most singularly successful regional planning agency in the world, has no separate planning board or division. The planning function is a part of the administrative process.

One principle here is that the planning process might well be used as an

administrative method for bringing the experts and the people into a new relationship, one which is essentially educational for all concerned. Only in this way can the layman's decision on social policy, or on how to meet his day to day problems of living, be flavored with the scientific information of the expert. Similarly, only through physical face-to-face contact with people's needs, where they occur, can the experts' judgments be tempered into consistency with social realities.

The process of group planning on the community, state, or regional level should be viewed as sowing the seed of social action, because if consensus is not reached at this point, through achieving an understanding of the issues and a clear choice of path of action, at some future point the lack of effective individual participation in group action will likely spell the failure of the enterprise.

A Regional Integrating Facility Is Essential

Out of the planning processes the new organizational forms grow, if any are needed; and the process for more integrated administration evolves. But unless there is some machinery for achieving the integration of the several phases of regional development, such a unified pattern will not be likely to evolve.

The Tennessee Valley Authority provided such machinery for its river valley region. The directors of the TVA have skillfully woven their program into the institutional structure of the Valley. Their philosophy and method differ little from the one just described.

But in the large southern United States, there has been no such integrating machinery. And there has been no amazing social progress such as can be witnessed in the Valley of the Tennessee. Today, however, the South offers one valuable case study of how, on a

rather high level of administrative organization, an attempt was made to provide educational and research agencies concerned with resource development with an integrating regional facility. It offers one example of how processes of regional development can be set in motion.

Since the late 1920's there has been accumulated an increasingly large volume of research dealing with the status and potentialities of the South's human, natural, and social resources. Today the South is probably the best documented area in the United States. In spite of much good work carried on by various federal and state agencies, as late as 1943 there was considerable question as to whether the great reservoir of research information was finding its way to the people who need it.

At that time, the American Council on Education appointed a Committee on Southern Regional Studies and Education, made up of research and educational experts, for the purpose of investigating this problem and recommending a course of action. This committee, rather than conduct the study by itself, invited thirty-eight influential educators, research specialists, and administrators to join with it in a regional conference at Gatlinburg, Tenn.

In short, it was found that the great masses of southern people were set apart from the existing wealth of facts. The reading level of books and pamphlets dealing with agriculture, housing, health, and other such problems was far above the reading ability of the people. There were few adequate textbooks on regional resources for public school students and teachers. And, perhaps most difficult of all, research and educational experts were not accustomed to working systematically with one another to see that each made his most effective contribution to public welfare. Badly needed were new methods and media of mass communication. The public

schools, the institutions of higher learning, and adult education agencies needed to make great strides to increase their effectiveness in advancing the competence of the people to use their potential resources. A new agriculture, new industry, better health, housing, and social relations were possible only if the people could find skill and opportunity to develop and release their energies.⁸

The committee, while continually working with groups of state agencies, set up a second Gatlinburg Conference. This time, 115 specialists in research, education, and administration came as official representatives of their respective agencies and institutions. There were 20 official representatives of regional agencies. The group studied the earlier findings, developed specific plans for cooperative regional projects for production of educational materials, teacher education programs, cooperation among resource development agencies and the public schools and colleges, and other such topics. Representatives from the states worked a part of the time as teams, evolving specific plans of action to begin on their return home.⁹

Through the process described here, increased interest and more effective action in resource development have evolved in the South. In each state and among the several states, a new pattern of concern over resource development is clearly evident. Today more than 650 state agencies and institutions and 38 regional organizations in the fields of research, education, administration, and industry are, through cooperative action, slowly weaving a new fabric of regional cooperation.

To do this, southern agencies have developed specific new tools of communication.¹⁰ The Southern Educational Film Production Service, located at the University of Georgia, but created and controlled by a regional board of directors, has been established. A Regional Materials Service has been set

up at George Peabody College for Teachers. A cooperative Regional Training Program in Public Administration is operated from the University of Alabama. Serving as a central clearing house and service agency in education for resource development, the Committee on Southern Regional Studies and Education has been put on a permanent operating basis. Its central office is located at the University of North Carolina, with other staff services provided by the University of Kentucky, George Peabody College for Teachers, and the Tennessee Valley Authority. The committee publishes a quarterly newsletter, *Resource-Use Education*, sponsors a Regional Training Program in Resource-Use Education, holds special institutes and conferences for state and regional groups, and furnishes consultation services to other state and regional agencies.

This program has drawn heavily on the "know how" of TVA. One ingredient the committee added was a broadened idea of resource-use education.¹¹ Rather than administer a program with new personnel and new machinery, it set out to induce the resource-use education idea to become a part of the philosophy and program of the multitude of agencies and institutions serving the region. The committee thus serves primarily as a facility for achieving cooperation among state and regional groups in research and education. The processes of regional integration were set into motion.

The objective and method of weaving new patterns of life into the productive system of the natural environment can be viewed as building from the specific to the general. In effect, it moves from the individual to the group, from the small group to the community, the community to the county, the county to the state, the state to the group-of-states regions, the regions, to the nation, and hence into world regions and the entire world.

Obviously regional programs are not set up that way but they can be administered in such a manner.¹² Given the regional integrating facility, the job becomes one of facilitating the flow of human energy through channels of expression in rural areas, in communities, on the farm, in the factory, in the church, and in the colleges and universities.

Dictatorships pass ideas and initiative from top to bottom, from elite leaders to herds of followers. This may be the quickest and temporarily the most effective method. Democracy must thrive on ideas springing from masses of people who, in turn, act in accordance with their own group decisions administered by their own chosen leaders.

Regional Development and the Educational Process

Planning, organization, and administration, as three phases of social engineering in a regional framework, can thus be seen as a broad process of public education. It aims to assist masses of people to act on information consistent with the resource-use principles and practices which science identifies as essential to the achievement of the maximum productive capacity of the region.

First, there must be a systematic flow of scientific information to the people through scientifically devised and used media and methods of mass communication. The important points of leadership in a regional fabric of effective communication with people include newspaper editors, radio experts, civic clubs, ministers, county farm agents, college professors, personnel of state and county health departments, state departments of conservation, state planning boards, state departments of education, and other such groups.

The agencies mentioned here also make up the major fabric of social

action in a region. The second phase rests on the extent to which these agencies or organizations succeed in integrating their efforts and those of the people into patterns of coöperative activity consistent with scientific information.

Both of these jobs go on concurrently and are continuous. A region is a dynamic, changing organism. Processes for its development must also be dynamic. Regional designs are kept in the process of constant change and adaptation by the integrating facility, such as a regional planning or development agency. Plans then serve merely as points of departure and general guides from which to work.

It has been noted that research to measure regional capacity is a team enterprise for natural and social scientists. Similarly, the planning and administration involved in achieving full environmental capacity is a team enterprise for research, education, and administration.

REGIONAL CAPACITY AND NATIONAL WELFARE

The United States is a nation of regions, as well as states. To the extent that the public administration of national programs flows only from Washington to the hinterland, the people and their local and state agencies and institutions will become progressively weakened. But likewise, the nation will become weakened if the people and their local agencies and institutions do not find the motivation and skill to cope with their problems in the broader regional, national, and international framework.

Regions serve as intermediary areas between state and nation. This provides a medium for decentralization in both formulation and administration of national programs. They serve as a framework for the integration of a stronger national welfare. Each region, both for its own welfare and the na-

tion's, must develop those economic and social patterns based upon resources, which make it best qualified to contribute to the nation and the world.

The systematic development of the total regional resources of America is the next great frontier in the task of applied science and government. The overall regional administrative framework probably will be slow in taking shape. Those agencies and leaders who believe that the strength of a democracy lies in the power of its people can begin to shape their public service programs toward releasing that power. The processes of regional development, from the scientist's point of view, are the processes of developing the health, initiative and skill of our people within the framework of their natural and social environment. If the spirit and the method of this point of view permeate the programs of all our agencies of public service, the composite regional framework may follow. This type of evolution would be a fitting symbol of the democratic process.

Medical Bibliographies Available

A series of selected bibliographies on medical care has recently been established by the Subcommittee on Medical Care of the Committee on Administrative Practice. Bibliographies on *Chronic Disease and Hospitals and Health Departments* have been prepared and are now available. The subcommittee also

has a limited supply of some of the publications listed in these bibliographies which will be distributed to those desiring them.

Requests for copies of either of the bibliographies should be directed to the Subcommittee on Medical Care, P. O. Box 5998, Bethesda, Md.

Regionalism in Relation to the Health of the Public*

CARL W. STROW, PH.D.

Research Council for Economic Security, Chicago, Ill.

HEALTH is an important factor in the efficiency and happiness of a people—consequently, it is valuable to measure it. Direct indices of health are death rates, mortality from particular diseases and groups of diseases, morbidity, disability rates, organic defects. The available data for these indices vary in completeness, accuracy, and efficiency as units of measurement. Besides, there are many indirect indices of health which include cultural elements related to health. There is no one perfect index of the state of health and, therefore, the health indices available must be employed as only approximate indicators.

HEALTH-SANITATION RANKING OF THE STATES

In a recent study,¹ an attempt was made to compile data for indices of health and health-related factors. A total of twenty-eight indices were set up which were thought to have some bearing on health problems. A health-sanitation index for the various states was constructed from infant death rates, death rates from tuberculosis, death rates from infectious and contagious diseases, and prevalence of sewerage connections and defective housing. The data used for this index were taken from the year 1940, since more complete material is available for that year and

it may also be considered as a pre-war year. It will be interesting to construct the averages for war years and especially for the first post-war year after economic and population readjustments have taken place. Changes in health institutions and programs as well as migration of population may change the future rates and ranking of the states in health status from those of 1940. Table 1 and Map 1 show the rank of states by quartiles and show a decided regional

distribution of the rankings. The table ranks the state with the most favorable health conditions as number 1 and so on to 48. These rankings are for data in the year 1940 and are also subject to the shortcomings of the ranking methods. In terms of this health-sanitation in-

* Presented before the Health Education Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946.

dex, there are conspicuous characterizations by regions. All states except one of the southeast region are in the fourth quartile. While two states of the southwest region are in the fourth quartile and two are in the third quartile, 89 per cent of the population of that region is in the fourth quartile. All except one of the states in the far west region belong to the first quartile but nearly all the region's population belong to that quartile. Six of the northeast states are in the first quartile and six in the second and third quartiles, but 86 per cent of the population of the region belongs to the first quartile. The middle states and the northwest regions have ranks in the first three quartiles but with the middle states having more favorable ranks.

A closer analysis of the regional distribution of state ranks reveals the following phenomena. There is heterogeneity among the states in all the regions although more in some regions than in others. Within each region are distinct sub-regions where the variant health conditions are probably due to climatic, cultural, or population conditions. The ranking of the states tends to change slowly away from certain territorial centers such as in the case of Missouri in relation to the southern territorial center, and New Hampshire and Maine in relation to the northeast center. The variations in health ranking between contiguous states in the same region suggest heterogeneous distribution of the natural forces affecting health or the creation by some individual states of more effective health controls. Complete detailed explanations of the variations in health status within regions and between states would require detailed research into the underlying factors affecting the health of the population.

SPECIFIC HEALTH INDICES

While much credence must be given

to the ranking and regional distribution of the states in terms of the generalized health-sanitation index used in the previous paragraphs, it should be checked against some of the more specific indices. Among these, the infant death rate is probably the best single index of the health of a people. Preservation of infant life depends not only upon effective public medical and sanitary controls but upon the health intelligence of the family and the community. For this first index, the number of infant deaths plus stillbirths per 1,000 live births plus stillbirths was employed for the year 1940. For a second index of the level of health, the death rate from tuberculosis was used. The fight against that disease has been of sufficient duration and successful enough so that high death rates in any region are likely to be indicative of lags in medical and environmental controls. Unfavorable physical environment and selective migration may be important factors affecting the death rate from tuberculosis in some regions. Another mortality index is the combined deaths from the following infectious and contagious diseases: typhoid, paratyphoid, scarlet fever, whooping cough, diphtheria, and malaria. Other contagious diseases might be used but they occur sporadically due to epidemics in particular areas and for particular years, whereas those used in this index are more subject to control. A fourth mortality index is the number of deaths per 100,000 population in the age group of 1 to 60 years of age. This is used as an index of health because it shows the ability of communities to keep their members alive up to the end of that age period. The average duration of life in years for the United States in 1939-1941 was 63.62 years.² Consequently, the deaths before 60 years of age constitute a measure of a state's effectiveness in preserving life within its borders. Here again, migration of weaker population

stock and the inclusion of accidental deaths may reduce the reliability of this index.

The states were ranked according to their scores from these four indices, with the lowest mortality rate ranked as 1 and the highest as 48 (see Table 2). Individual states vary considerably in relative ranks on these four indices. However, there is much similarity in relative ranks; there are positive coefficients of correlation among these four mortality indices for the states ranging from $+0.5$ to $+0.9$. The highest positive correlation is between infant mortality and death rate from infectious and contagious diseases.

The states may be classified as to their variations in ranks on these four mortality indices. First are 16 states which have nearly equal ranks, whether high or low, for all the indices; viz., Minnesota, Wisconsin, Indiana, Montana, Ohio, Missouri, Colorado, Virginia, Florida, Alabama, Mississippi, Louisiana, Arizona, Tennessee, Texas, and Georgia. These might be called the homogeneous states. A second class includes those states which have nearly equal ranks on two indices and nearly equal ranks on the other two but with considerable numerical difference in rank between the two pairs. Such are Connecticut, Nebraska, Kansas, Idaho, North Dakota, Vermont, Delaware, Maine, Kentucky, and North Carolina. A third group of states has three ranks nearly equal on three indices but with the fourth rank varying considerably from the other three. Such states include Oregon, South Dakota, Iowa, Wyoming, Rhode Island, New Hampshire, Oklahoma, New York, Maryland, West Virginia, South Carolina, and New Mexico.

In the case of the second and third groups of states, it is probably the existence of one or two variant causes such as population elements or health controls which account for the distribu-

tion of ranks. A last group of states consists of those with ranks varying for all four mortality indices. These states are: California, Washington, Utah, Illinois, New Jersey, Massachusetts, Michigan, Nevada, Pennsylvania, and Arkansas. They may be designated as the heterogeneous states and contain a variety of conditions which act as factors in the health of the respective state populations. Such health related factors are important in a regional analysis of the United States and will be given more attention in later pages. These data are only more proof of the heterogeneity of health conditions and health factors in a wide area such as the United States. Of course, that condition means plural health conditions but regional analysis will give a better overall picture.

REGIONS OF THE UNITED STATES

Even a casual observation of the rates and ranks of Table 2 gives the impression that there are territorial patterns among the 48 states. Accordingly, in order to show the regional distribution, the states were grouped in quartiles according to rank and marked upon a map of the United States. Maps 2, 3, 4, and 5 showing indices of mortality are the result, and from them a picture of health regionalism may be obtained.

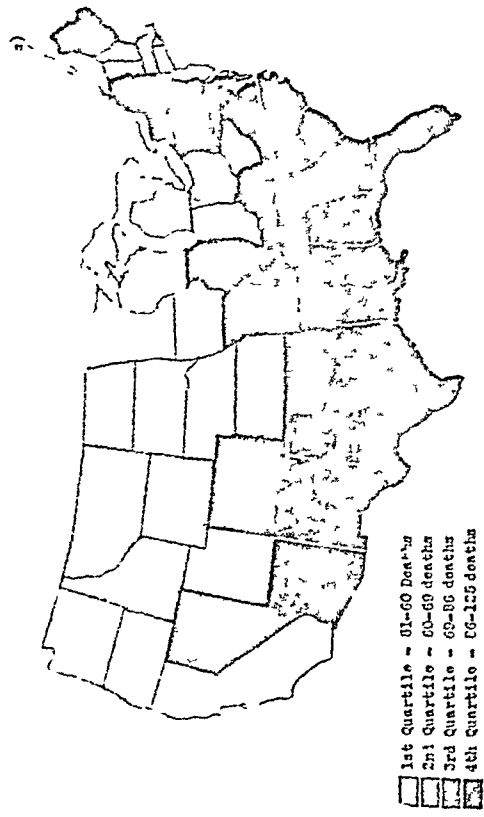

From Map 2 it is noticeable that all the southeast states except two are in the fourth quartile. All except one of the southwest states lie in the fourth quartile. On the other hand, all except one of the far west states are in the first quartile, i.e., those with low rates of infant mortality. The other three regions have mixed rankings among their states with adjacent states located in the central part of each region differing slightly in mortality rates but with wider differences in rates in the case of states located on the margins of regions.

Map 3 shows the regional distribution of tuberculosis mortality following a ter-

MAP 1—BIRTH-AND-DEATH RISK OF STATES—1940

MAP 2—INFANT MORTALITY—1940
(Infant Deaths plus Stillbirths per 1,000 Live Births plus Stillbirths)

MAP 3—DEATHS FROM TUBERCULOSIS PER 100,000 POPULATION—1940

MAP 4—DEATH RATE FROM SIX INFECTIOUS AND CONTAGIOUS DISEASES—1940
(Deaths per 100,000 Population)

ritorial pattern quite similar to that of infant mortality. However, the southeast region has a somewhat lower ranking on this index, while the high mortality rate for tuberculosis in California is probably due to the migration into that state of tuberculars or potential tuberculars. The industrial states of Illinois and New York have higher rates than other states in their regions, probably due to effects of urban life or other local conditions.

The distribution of ranks for mortality from the selected infectious and contagious diseases is depicted on Map 4. The territorial pattern follows closely that for infant mortality except that the older industrial states have lower rates on this index. This is due to more complete medical care, sanitary facilities, and disease control in those states. Since climate is an important factor in this group of diseases, that cause must be kept in mind as explaining the ranks of some states.

The regional pattern of Map 5, which shows the quartile ranking of the states with respect to mortality in the age group 1 to 60 years of age, is similar to the other mortality index maps. The southeast region is largely in the fourth quartile of states while the southwest region has a better record but with individual states ranking in all four quartiles. The northwest region has a very favorable record with all except two states in the first quartile. This high status seems to be associated with a wholesome rural environment and a vigorous population stock. The far west region has state rankings chiefly in the third and fourth quartiles, probably due to migration into it of potential cases of mortality. Many of the industrial states as well as those advanced in culture and wealth have higher mortality rates in the age group 1 to 60 years than the rural and newer states. This is probably due to the occupational and daily hazards of industrial

urban life and to migration into such states of persons who are higher mortality risks.

At this point a word should be interjected as to the use of statistics in such problems as have been treated in the preceding pages. There are numerous shortcomings in the application of statistical methods to human phenomena. In attempting comparisons between states, it is slightly misleading to apply ranks to states or to assign them to class-groups. Thus, differences in mortality rates may not be commensurate to the difference in ranks assigned them. The last state in one quartile may differ very slightly from the first state in the next quartile. All mortality indices are only approximate or partial measures of the health of a people since numerous adjustments must be made for population composition. Moreover, preventive and curative medical care may be lavished upon cases nearest death to the neglect of other segments of the population. Mortality statistics are still subject to error—due to incomplete registration and errors or variations in diagnosis of the causes of death. The health of a population is many-sided; some elements are all important while others are trivial. One disease may be much more damaging than another, and one type of malfunction may entail more physical and economic losses than another. Therefore health indices vary in their significance.

REGIONAL HEALTH FACTORS

As mentioned previously, the regional pattern of the states in terms of health-related factors and mortality indices is not one of perfect symmetry. Especially do we find cases of contiguous states varying considerably in rank. This gives rise to the hypothesis that numerous factors act in an accentuated degree to influence health conditions in certain individual states and areas. A brief

outline of such factors is given but with no attempt at complete analysis. Minute research is necessary to discover the operation of those factors in the regions and sub-regions of the United States.

Climate—There is much diversity of opinion as to climatic effects upon health. As a general rule, health, inclination to work, and social progress follow the same geographic distribution. Climate has direct effects upon the human organism as well as indirect influences through its effects upon the soil, the fauna and flora, occupations, and economic goods. These influences play their part in determining the health of various states and the relative rank of the regions of this country. Temperature and humidity may be conducive to specific diseases such as pneumonia or malaria as well as have indirect effects upon organic resistance. Warmer climates may promote the growth of insects, bacteria, and other parasites which are associated with infectious diseases. This seems to be the case of the southeast and southwest regions. However, a favorable climate may lower the health record of a state by attracting to its territory weaker population elements and those already afflicted with diseases. The states of California and Florida are examples.

Population—The processes of migration and selection may affect the health status of the various states. A common claim is that the westward migration in this country has given the central and western states a healthier population because of attracting the hardier elements to migrate to those territories. The health ranks of California and adjacent states have been influenced by the migration into their territories of tuberculars and invalids—those who migrate "for their health." Racial and nationality composition also may be associated with health rankings chiefly through economic and cultural status or because

of a lack of assimilation. A common conclusion is that the Mexican and Negro elements lower the health ranks of the southern and southwest states. By comparing the infant mortality ranks of the states as given in Table 2 for the entire population of each state with the ranks of the states for the white population alone, it is found that, of the 14 states having the highest percentages of non-white population, the ranks are lowered for 11 states and raised for 3 states when the rates for the white population alone are used—or a change of nearly five in average rank. Map 6 shows the regional distribution of infant mortality for the white population of the states. The most conspicuous change is the appearance of two north-eastern states in the last quartile. However, with some variations, the regional pattern of infant mortality ranks is much the same as on Map 2.

Public Health and Medical Care—In another study,³ the coefficient of correlation between medical facilities and mortality rates was found to be significant ($+0.6$), i.e., the more medical facilities, the lower the combined mortality from infant deaths, tuberculosis, infectious, and contagious diseases. However, there are many factors which account for the distribution of medical facilities over the United States. The per capita expenditure for public health by state governments does not have a significant correlation with the above mortality indices. There is no question about the value of public health programs, but it is difficult to find indices which will measure fully such values. The public health movement is so well developed that it stands so much to prevent what might happen and does not therefore show up in many comparative statistics. There is a worth while field for research into indices which will measure the effectiveness of public health controls. There is another interesting feature of the varying need for public health

activities among the states. It seems that more complex cultures create perils to the health of their populations which, accordingly, will require additional defenses against the new dangers. For instance, data will show large cities with favorable health conditions. However, to maintain a high level of health, it

becomes necessary for the city to spend a sizeable portion of its economic product for protection against the health hazards created by urbanism. This may explain the high health ranks of some rural states where a vigorous population not highly congested and living in a wholesome natural environ-

ment does not need as many health and sanitary controls.

Economic Resources—There is a high positive correlation between economic resources and factors conducive to good health. Map 7 shows a decided regional distribution of economic resources—per capita wealth, income, and savings—with all except one of the southern states in the quartile of lowest economic resources. The urban industrial states have the most resources, with rural states much lower. Economic resources and health ranking follow each other quite closely with the exception of California and New York ranking relatively lower in health than in wealth and income, while the west north central states have better records in health than in economic resources.

Wealth and income are means to better health since they mean purchasing power to obtain wholesome commodities, medical services, medical and sanitary facilities, as well as to support public health activities. They are also influential in maintaining a wholesome diet—a factor of tremendous importance in the health of a people. But there are several limitations upon the apparent value of high wealth and income. How wealth is distributed within a population and how used are variable factors. High wealth and income create some conditions inimical to health, such as luxurious, idle living, urban congestion, and the strain of a highly mobile life. It is obvious that relative health needs, the price system and modes of rendering health services are factors in determining the values of economic resources in securing aids to better health for the population.

Culture—It is difficult to construct indices of the cultural level in its relations to health. Such an attempt was made⁴ by using literacy, high school enrollment, school expenditure, governmental expenditures for recreation, and proportions of professional persons in

the labor force. Many others might be used but statistics by states are not available for all. Map 8 gives the regional pattern of the states in terms of the above index of culture, which follows closely that for economic resources but with exceptions in the case of several adjacent states. These variations show that cultural achievement is not entirely dependent upon economic strength.

The cultural level of a state is of importance in achieving and maintaining high health standards. Advanced culture in a people means an appreciation of the health factor in their lives; it means a demand for medical and sanitary services along with their intelligent use; it will emphasize the preventive aspects of health programs; it furnishes the capacity for the assimilation of public health education.

The close connections discovered to exist among health-related factors leads one to suggest that they constitute a definite culture complex in American society. The cluster of activities, programs, laws, traits, and institutions make up the health complex, within which there are patterns of interrelationships. These reciprocal influences as products of social evolution in this country should be considered in all health planning. Improvement in the health of the population will require action and reconstruction of those processes and institutions which are interrelated with existent health conditions. It is too long a story to enter into the details of this problem. Probably, the most outstanding conclusion from the correlations pointed out so far is the high degree of coincidence between favorable health status and the economic-cultural factors. This is to be suspected in the case of the United States. Briefly it means that, in order to obtain improvement in health, economic and cultural reorganization and reconstruction must be effected along some lines. It is necessary to recognize the economic

law that the greatest benefits of commodities tend to go to those parts of a country where culture is the highest and wealth is most abundant.

THE HEALTH REGION

The region is now a well accepted concept. In general terms it is thought of as a large area with natural boundaries wherein there are many resemblances among the inhabitants and their culture. Use of regional analysis has proved especially useful in a country like the United States with its diverse conditions and resources as well as because of the large number of its local and state governmental units.

"Health region" as a concept may also be used. Health regions are those major areas with distinct health conditions identifiable with the areal limits and caused by the natural and human factors operating within the natural boundaries. Such regions must stand out as distinct but are not completely different from each other. Moreover, their boundaries will shift with changes in the health-related factors.

There are many values to a regional measurement of health conditions.

1. It can define the situation, show the location of problems, the area, population, and extent of conditions.

2. It can reveal some of the causal factors. The ecological analysis can point out the rôle of climate, geography, pests, bacteria, and other enemies of health, the rôles of economic and social institutions with respect to communities and states.

3. It can create a civic consciousness toward health problems. A community or region may be made aware of its condition not only in relation to its own problems, but also in comparison with other regions. Such comparisons should not be condemnatory but only for the purpose of showing need for action.

4. It can point out definitely where conditions need improvement and enable medical planning to go immediately to the location of trouble. Programs for better medical care and public health measures can be adjusted to meet each concrete situation.

A survey of regions by health indices shows above all the variety and complexity of health conditions in the United States. Various sub-regions have their own special conditions and the problems of the nation cannot be described in one flat statement. Economic resources, cultural organization, and political divisions must be considered when planning health controls. To deal with regional health problems, it is necessary to inquire into the relations between man and his physical environment and into those phases of culture which function as controls upon the forces related to health.

There are different types of health regions. There is no standard classification of them since they may be grouped under either the actual health conditions or under the factors producing the conditions. Such a wide variety of types would include: climatic types such as sea-coast, plains areas, sub-tropical zones; regions characterized by particular diseases such as tuberculous areas, infant mortality regions, goiter belts, trachoma areas; population types such as Negro areas, Mexican areas, defective population zones, isolated regions; economic-culture types such as underprivileged regions; deficient medical care areas; regions with deficient sanitation. The mortality from heart disease, cancer, diabetes, and similar diseases varies by state and region. Detailed studies of such distribution will show that population composition, types of consumption, economic and cultural traits, and differences in disease diagnosis are the chief factors causing the regional variations. If states are identified with or belong to types of health regions, such regional analysis may be of value along several different lines. First, it may be pointed out how the health status is influenced or perpetuated by the environment and culture of a region. Second, such analysis locates health problems and may become

the basis for health programs, health districts, public health education, and administrative organization.

REGIONAL REORGANIZATION

Regional health surveys of the United States show some definite areas with subnormal health conditions which may be designated as underprivileged regions. Such are the southeast and southwest regions together with subregions in other parts of the country. How should these regional inequalities be dealt with? This is a pressing problem in the United States since equality of opportunity applies also to health. Although health indices show differentials in health conditions among the states over some period of time, there is no justification for the perpetuation of preventable deaths, disease, and disability in one region while vigorous infants and healthy adults live in another region. The American creed would not assume ill-health as a permanent characteristic of any region; rather it assumes the possibility of health control over environment and culture.

Since some regions must be aided to attain higher health levels, there are two main lines of attack: (1) by means of a shifting of financial resources from the more advantaged to the less advantaged regions, (2) by an economic and cultural reconstruction of the underprivileged regions. The first might be accomplished by public subsidies to states needing aid in health controls and services, by forms of nationalizing medical services and facilities with financial support from a national budget, or by foundations providing medical services and research where the local economy cannot support such. Economic and cultural reconstruction must seek such measures as readjustment of population composition, such as supply and human fertility differentials of the population, more effective and increased utilization of the region's resources, general educa-

tion of both juveniles and adults, and public health education. More specific measures would be agricultural adjustments, social-industrial improvements, reintegration of rural life into modern American culture, higher standards among racial elements of the population, redistribution of economic opportunities, and improvement of the folk culture.

All the suggestions for reorganizing regional health conditions constitute a large order. What limitations are there to such programs and how much is possible? To establish an equilibrium between population and resources is a long process since it must effect changes in the organic life of society. The whole problem is how to deal with human resources and natural resources in their relations to health problems. Both, for instance, are factors in providing medical services and facilities, the financial support coming from the economic-natural resources and human talents from the human resources. Effectiveness in reconstructing the internal factors of a region is limited by the time element; it takes time for processes to show results. Another shortcoming is man's ignorance of and skill in the technique of human reconstruction.

How far can or should resources be shifted into underprivileged health regions? Here again, there are limitations. It may be the age-old problem of taking from some to aid others; and elevation of one region at the expense of others can hardly be recommended as a permanent policy. Public opinion will determine the policies with respect to shifting of financial aid. It will be too much to expect that the same levels of health can be quickly established in all regions because many of the varying conditions over a diverse area like the United States are too fundamental to admit of quick change. How much action should be taken in aiding any underprivileged region by means of shifting financial aid depends upon: (1)

the relative importance of the health factor in human life, (2) the importance and efficiency of the particular measure for improvement of health conditions, (3) the obstacles to health progress such as climate, ignorance, etc., and (4) the extent to which there is an interdependent economy among the regions of the country, i.e., labor and enterprise of one region contribute to the wealth and income of another region. This would justify the financing of some of the social services by the economy of the country as a whole.

In dealing with the health of the public, an evaluation of means must be made. This study has shown that regionalism may be used as a technique by society for dealing with some problems where the forces are closely tied in with regional characteristics. Society, therefore, may sometimes use the regional approach in administration and control but at other times should not. There should be flexibility in the selection and use of social measures, controls, and institutions. Public health officials can employ the regional approach and seek to fit their programs to the problems and culture of the various regions. Consideration must be given to the pre-

vailing folkways and mores of a region. To be effective, public health education must utilize the characteristic modes of communication within a region, putting its message into the language and literature of the people.

Of course, the use of the region in health organization is limited because of the conflict between political and regional boundaries. Political units must be used very often but their programs must take into account the regional characteristics. In some cases, the health programs of the political units of a region may be synchronized through coöperative action. Physicians, specialists, hospitals, etc., might be distributed with special regard to the needs of regions and sub-regions; sanitary engineering must operate by regions in some cases and might in others; medical schools and medical research may serve regions by means of coöperation among states.

Lederle Renews Tick Fever Grant

Lederle Laboratories has renewed its grant of \$2,400 to the University of Colorado School of Medicine, Denver, for continuing research on Colorado tick fever. Under the direction of Dr. Lloyd J. Florio, Professor of Public

Health and Laboratory Diagnosis, studies will be continued to try to determine how the disease is spread, whether it exists in other areas and whether the virus can be isolated in nature.

Municipal Public Health Engineering*

Data on Current and Proposed Local Sanitation Divisions

Engineering Section

A NEED exists in the field of public health engineering for the establishment of acceptable criteria on functions, cost, salary scales of engineers and sanitarians, and the quantitative relationship of such personnel to populations served and work performed. As a first step in this direction, the Committee on Engineering Administrative Practice of the Conference of Municipal Public Health Engineers has circulated questionnaires and compiled the resulting data. A summary of these data and comments thereon are being submitted as the report of the Engineering Section Committee on Municipal Public Health Engineering, the personnel of which is substantially the same as that of the Committee on Engineering Administrative practice.

The need for such information became acutely apparent upon the publication of the report, *Local Health Units for the Nation*, commonly spoken of as, "The Emerson report," in recognition of its author, Dr. Haven Emerson. This report, prepared without general engineering consultation or review, nevertheless, recognized the principle of engineering direction of all work in the public health control of the environment, and outlined the greater and more universal use of engineers in administering the environmental sanitation program of local health departments. The sharp reaction to the report by many engineers and sanitarians resulted from the fact

that the minimum sanitation program and personnel recommended in the report has been misinterpreted in some quarters as an authoritative proposal for an adequate program and budget, and as a consequence, has unfortunately and unintentionally, complicated the struggle of local engineering administrators in a number of places in achieving an adequate and balanced program in relation to community requirements and other departmental functions.

In general, few, if any, of existing local environmental sanitation divisions at the larger population levels are adequately organized or properly staffed. This is due to the fact that engineers, on whom effective local sanitation work depends, only recently have been employed in significant numbers. Eleven of the 17 bureaus of environmental sanitation represented by the data here presented have been organized since 1930. The few engineers engaged have had a herculean task in introducing a technical approach to the work and securing suitable personnel, or training old employees to become passable sanitarians. Rarely have circumstances existed where an experienced public health engineer could initially plan a theoretically desirable division and then bring it into being without major excisions and concessions to expediency—financial and political. Furthermore, should the engineer look around for some pattern of organization for such

a division, he would have difficulty in finding any data or literature expressing agreement of other engineers on the type of personnel required, the per capita cost of the program, or the population to be served per employee.

Early reports prepared by or in cooperation with the A.P.H.A. Committee on Administrative Practice, published in 1926¹ and 1932,² and of the American Child Health Association,³ published in 1925, made only incidental reference to the employment of sanitary engineers in local health departments. The report of the Committee on Administrative Practice, published in 1939,⁴ made a radical departure from preceding reports in recommending professionally qualified personnel for directing environmental sanitation programs and specifically recognized the possibility that sanitary engineers might serve in such positions. But even that report, published only seven years ago, recommended a salary range for such directors of only 75 per cent of the range suggested for nursing directors.

The report of the present Committee on Municipal Public Health Engineering is submitted, therefore, to focus thinking on these problems and to present some figures pointing the way to further study and conclusions.

A questionnaire dealing with current personnel figures, costs, and functions of their environmental sanitation divisions was circulated to a limited number of public health engineers. Seventeen responses were received. These engineers had an average public health experience of 15½ years, with an average time in present positions of 9 years. This gives some indication of the soundness of their judgment. An effort was made to establish a percentage relationship between the salary of the chief engineer and the health officer, and to determine what environmental sanitation control functions, if any, were not under engineering direction. The indi-

cations of functions being performed were not meaningful because of varying interpretations of the questionnaire and the limited number of responses. However, data on per capita costs of environmental sanitation programs and numbers of personnel in relation to the population covered were useful, particularly as tabulated from information submitted in a second questionnaire.

The second questionnaire asked for the engineer's concept of an adequate and satisfactory environmental sanitation division for population levels of 25,000, 50,000, 100,000, 250,000, 500,000, and 1,000,000. Three of the six forms used in the study were sent to each of fifty-four engineer-directors, each receiving the form corresponding to the current population of his health unit and, wherever possible, the forms for the two population groups next smaller. The theoretical units were considered as consisting of a city-county district with the city predominant in population. For each unit, the salary of the health officer was given in order that environmental sanitation salary ranges might be related to it. The health officer salaries were assumed to be respectively, \$4,000, \$5,000, \$6,000, \$7,500, \$8,500, and \$10,000, for the population units mentioned above.

Those receiving the questionnaire were requested to state their concept of an adequate division of environmental sanitation conforming to the best current practice, related to their present geographical locations, and disregarding the one dollar per capita overall cost limitation. Laboratory and labor costs, if reported, were excluded from the totals in compiling the data. In determining the total salary cost, the median of the salary range of each position was used.

Seventy-four responses were made by 34 engineers or division heads. These were tabulated by population levels and

further grouped as to geographical region, i.e., South, North Central, West and East. As in all such data, there were extremes and abnormalities in some of the reports which unduly influenced the averages. However, in the summation of the averages, there was a surprisingly smooth pattern of curves and consistency in the figures on per capita costs and population per employee.

From Table 1, "Summary of Data" the sequence of positions and salary ranges, as derived from the individual responses, will be apparent. It was painfully obvious, from some of the proposals, that several engineers do not appreciate their importance in the public health field or their relative value in terms of salary. A very few responses indicated that the engineer considered himself worth only half the health officer's pay. Assuming that the engineer is capable and effective in his job and that a rational professional relationship exists between the engineer-director and the health officer, the engineer's pay should be governed by the fact that he administers work lying outside the physician's field of professional competence. The engineering profession is parallel and not subordinate to the medical, and the engineer-director should ordinarily command the second highest salary in the department, there being no quarrel with the medical executive tradition.

From the summary of data, it will be seen that the averages of minimum and maximum engineer salaries ranged from 65 per cent to 80 per cent of the average of the health officers' salaries, the latter being intended to represent a fixed maximum. These are significant figures and deserve to be kept in mind. In the seventeen cities and districts reporting, where the environmental sanitation directors are old employees and presumably at their maximum salary range, their pay averages 62 per cent of

the health officers' salaries. Ten of these seventeen departments have budgets exceeding \$1 per capita. Until engineers themselves generally evaluate their services at their true professional and social worth, they cannot expect fair relative compensation. Furthermore, a depressed salary for the engineer means reduced scales of pay for all subordinates, and consequent difficulty in attracting and retaining competent sanitarians and technicians.

Of major interest are the figures on estimated per capita costs of the environmental sanitation program. There is surprising uniformity for all population levels. The average of 33 cents per capita is another significant item. With \$1 per capita ceiling, largely self-imposed by public health authorities, and with approximately 50 per cent of the local budget allotted to nursing services, it is obvious that the budget must be increased or sanitation and other services will suffer. Needless to say, sanitation expenditures which equal 33 cents are a rare exception other than in the South where labor costs of mosquito and rodent control are included. Among four cities with populations ranging from 208,000 to 300,000, that reported actual costs, two in the South spent over 50 per cent of their budgets on environmental sanitation, thus accounting for the 33.2 cents per capita for this group.

Engineering administrators should think in terms of the overall cost of sanitation and so be in a position to advocate a general health budget with a definite and adequate share for environmental sanitation.

Closely related to per capita cost is the population load per environmental sanitation program employee. While the reports recommend on the average 1 environmental sanitation employee per 13,530 population, regional differences are apparent in the basic data. Population loads in the South generally averaged 11,700 as contrasted to 16,700 in

a. A Grade 3 was also recommended for these communities; a total of 4 engineers with a salary range between \$3,000 and \$3,600

b. Engineer-Directors' salaries' average 65 to 80 per cent of Health Officers' salaries

TABLE 2

Percentage Relation of Salary of Engineer Director of Environmental Sanitation to Health Officer's Salary, 17 Municipal Health Departments

Population	Number of Departments	Engineer's Salary as a Percentage of Health Officer's Salary	Sanitation Division	
			Per Capita Expenditures	Population per Employee
90,000- 100,000	3	62	\$0.510 ^a	12,000
208,000- 300,000	4	61	0.332	11,500
456,225- 492,370	2	65	0.154	21,000
816,000-7,700,000	6	62	0.194	19,500

a. Includes one Southern City with 40 per cent of a \$3 per capita budget for sanitation.

the North Central area. This may be compared to the Emerson report minimum proposals wherein environmental sanitation program loads varied from 21,000 to 36,000, without any geographical distinctions.

Such figures on population load are much less valuable and applicable in the field of environmental sanitation than in the medical and nursing activities where the individual is the basic unit. In an environmental sanitation program, many factors such as climate, geography, industry, density of population, and political structure affect the functions and work load. These factors are complex and extremely variable, so that no precise pattern may ever be prescribed which will have general application. However, with further study, a basic population load might be established with modifying coefficients which would be useful as a guide.

The question of work load, in terms of population served per employee and with reference to routine activities, has received attention on the part of several groups but has been neglected by those most concerned, the engineering administrators. The U.S.P.H.S. Division of Public Health Methods, reporting in *Public Health Reports* of June 14, 1946, on the findings of a study of 933 full-time local health departments, gives the median ratio of population per nurse position as 10,800; and the ratio per sanitation position as 24,800. In subsequent discussion this report refers to

the Emerson recommendations and points to a 50 per cent deficiency in nursing personnel and an overall adequacy of sanitation positions. It is difficult to follow such reasoning, except in view of the commendable job performed by the nursing profession in urging small population work loads. Former reports of the Committee on Administrative Practice (previously cited), in recommendations not limited by the \$1 ceiling, suggest sanitation budgets of 20-25 cents per capita, and list desirable activities to include: city planning, supervision of water supplies and sewage disposal, housing, sanitation of public buildings, industrial establishments, swimming pools, beaches, barber shops, fly, mosquito and rodent control, supervision of school sanitation, food and milk control, but exclude plumbing, cross-connections, and private sewage disposal, and provide for meat inspection costs to be supported by fees.

These reports, and they are not very old, would seem to favor a reduced emphasis on the environmental sanitation program as related to other activities on the basis that general nuisance control has been a wasteful and unjustifiable activity. This is a consequence of little or no recognition being accorded the newer technical and epidemiologically sound activities that have been confronting environmental sanitation personnel in recent years, just as in public health nursing the routine placarding of

all communicable diseases has been supplanted by other activities.

Other factors of major importance that need further study are: personnel organization and supervision, competence of the individual employees, specialized versus generalized field work, etc. An urgent need exists for detailed and widespread time studies, under engineering direction, of the field work of the sanitarians for every routine function. Methods and formulae for the evaluation of environmental sanitation activities and programs are similarly needed. Only information of this character will enable engineering administrators to arrive at sound conclusions as to personnel requirements.

The several groups of engineers now exploring the factors of and personnel requirements in an environmental sanitation program should push forward their work and should enlist the aid of every official and public health agency in a position to assist in the detailed studies. Engineers in the public health field should feel keenly their professional responsibility in furthering such efforts and in clarifying and defining their part in the public health program so that their findings may be authoritative and widely accepted.

SUMMARY

1. Acceptable criteria need to be established by public health engineers for local environmental sanitation divisions as to personnel requirements, salary ranges, costs, and work loads.

2. Data are presented as secured and compiled by the Committee on Engineering Administrative Practice of the Conference of Municipal Public Health Engineers, such data

consisting of responses to two questionnaires, one on *existing* local environmental sanitation divisions and the other on *proposed fully effective* divisions for population units of 25,000, 50,000, 100,000, 250,000, 500,000, and 1,000,000.

3. In the proposed sanitation divisions, engineer-director salaries ranged from 65 to 80 per cent of the corresponding health officers' salaries, whereas in established departments, engineers' salaries, after long employment, averaged only 62 per cent.

4. Per capita costs for environmental sanitation programs averaged 33 cents in the proposed divisions, with higher costs in the South and lesser costs in the East and the North Central areas.

5. Population loads per employee in the proposed divisions averaged 13,530, with a range from south to north of 11,700 to 16,700, respectively, as compared to population loads of 21,000 to 36,000 in the Emerson report, where no geographical distinctions were made.

6. Engineers are urged to proceed promptly to the development of criteria which can be accepted and used as the basis for further development of local public health engineering work.

PAUL F. ELLIS *

United Press Science Writer

WHEN President Truman made the historic and fateful announcement that America had built an atomic bomb and had dropped it on the Japanese city of Hiroshima on August 6, 1945, most Americans did not realize that they were being snapped out of a deep sleep.

The start of the atomic age found the average American—and for that matter the average citizen in any country—with a sleepy knowledge of the part that science really had in his health, his happiness, his fate.

Mankind for centuries has sought health; what to do to make this short life on earth as happy as can be and prolong it as much as possible. But in all the years Mr. Average Man left such problems to those with whom he believed he had no common language. When the atomic bomb dropped on Hiroshima demonstrating in an awesome way just how human fate is wrapped up in science, there came a new awakening.

The people of this country really became interested in science, not alone interested in the science of making atomic bombs. Mr. Average Man wants to know why, if science can make a bomb that will destroy tens of thousands of lives in seconds, science cannot save lives, make people happy through health, and prolong both health and life.

There are many thousands of Americans today who believe that if science can spend two billion dollars to build an atomic bomb, then why in goodness name can't a cure for cancer be bought for a similar sum, or less. This is mentioned as an example of the consciousness of the American toward the part he believes that science—and here we are approaching medical science—can play in his welfare.

It cannot be denied—it should be emphasized—that the average American today is more interested in his health than ever before. The American today will go more than half way with health officials if he is given the chance.

The American Public Health Association is one of the nation's oldest and most respected organizations that have helped to keep this cosmopolitan nation the greatest in the world. With its own cosmopolitan membership, it is an organization that springs from and represents the grass roots of America.

The organization's great work is recognized by the profession—those who are "in the know." The time has now come, however, when this Association can dramatize the renewed interest in science created by the war to get its health message to every corner of the country. Not only must it realize the importance of public education, as it does in common with many other professional organizations, but it must make the climate in which this education can be widespread and result in effective action. As an example, the average American today is more conscious of the problems and the coöperation needed to control cancer than ever

* Mr. Ellis is the Science Writer of the United Press. In this capacity he attended the 74th annual meeting of the Association in Cleveland. He and other press representatives who were present at that meeting regretted what they regarded as an indifferent attitude of the program speakers toward reaching the public. He was invited to bring his impressions and those of his newspaper colleagues to the first meeting of the 1947 Program Committee in the hope that the speakers on the coming Atlantic City program could be induced to accept greater responsibility for sharing their information with a wide public.

before. This has been the result of much-too-recent campaigns to educate the public on cancer.

Another example is the National Tuberculosis Association. Statistics show that while tuberculosis still is a menace to American health, this disease is being brought under control, due in great part to public education.

Still another example is the National Foundation for Infantile Paralysis. While some progress has been made toward controlling this disease, the Foundation undoubtedly will do even a greater job in public education and ultimately win a great victory. Within the last year the Foundation assisted this writer in visiting many of the nation's top laboratories, which it is helping financially, and to have a free hand in reporting for the United Press just what is being done on polio. The response to this series of stories published in the lay press was outstanding. It was an example of how medical science can cooperate with the lay press to meet the cooperation from the lay public in a natural, but latent, desire for knowledge.

The American Public Health Association with its many affiliated organizations can be made a great information center for the American public, particularly on the science of preventive medicine. This Association with its long standing as a recognized major force in public health, could come out now with literally both fists swinging to knock down the barrier separating the average man and those who have the responsibility of keeping this nation healthy. The Association could make its annual meeting a major scientific news story of the year. The participants in the discussions could slant their reports and papers toward the minds of 140,000,000 Americans--and not exclusively to the circle of learned men and women in the profession. This means foregoing ten dollar words and sixty-four dollar ques-

tions. It means making papers or abstracts—that really abstract the highlights—available to the press in time to be presented to the public, accurately and effectively.

The Association could help the "recalcitrants" to see the light that the average man wants to guide him toward cooperation with public health authorities in the quest for a life that will continue its natural course free from disease.

There is no better example of this desire to cooperate on the part of the public than during the smallpox scare in New York City last spring. Some 2,000,000 persons submitted themselves for vaccination. They had been properly educated. The health officials had talked their language. What might have been a serious epidemic was averted.

The science writer of the press services and the newspapers is very close to Mr. Average Man—in fact, is one. He realizes his responsibility in reporting accurately the news of medicine. The conscientious science writer does not seek to sensationalize. He seeks to be a good reporter; to tell his story in words that Mr. Average Man understands.

The cooperation between science writer and scientist is growing all the time. Many scientific organizations now realize the value of the lay press, particularly the science writer, in carrying their messages to the public. Without this support scientists could not exist in this fast moving scientific age.

The American people deserve to know what the members of this Association have found about the best methods of organizing their local health departments, the most effective methods of finding, curing, and preventing communicable diseases, the best handling of sewage and other wastes, the best organization of a child health program. They demand such education. The American Public Health Association can, if its members so will, play a great part in this new education for a new age.

TWO NINTHS

THE 9th Edition (1946) of *Standard Methods for the Examination of Water and Sewage*—already in print—and the 9th Edition of *Standard Methods for the Examination of Dairy Products*—shortly forthcoming, with a 1947 date line—are links in a long chain of publications, the texts of which are perhaps as well known to many readers of the *Journal* as are familiar passages of Holy Writ. These volumes are essential elements of the very life blood of the American Public Health Association. Its standing Committee on Research and Standards, its Coordinating Committee on Standard Methods, and the devoted committee members concerned have given unstintedly of themselves to the task of making each of these books the best in its series over a long period of years and the outstanding publication in its field anywhere in the world. The unusual merits of each of these "Ninths" will be fully realized only by those whose activities require frequent use of one or both of them. Although both books have been prepared under the stress of war, never before has so much consultation, deliberation, and review gone into an edition of either the "Water" or the "Milk" report, with the result that both volumes should better represent than do any previous editions the opinions of the members of the Association as a whole. Since, in their preparation, both manuscripts benefited from extensive collaboration with other national and international associations through appropriate committees, the volumes epitomize the viewpoints held by experts in these fields of endeavor throughout the territory the Association serves.

The 9th Edition of *Standard Methods for the Examination of Water and Sewage* has been prepared, approved, and published jointly by the American Public Health Association and the American Water Works Association, with active participation by committees of the Federation of Sewage Works Associations and the American Chemical Society. Great credit goes to Dr. John F. Norton who as chairman of the Joint Editorial Committee carried the torch that directed the way to accomplishment.

The style of the new edition of the water and sewage report has been different from that of preceding editions; many persons who have seen the publication consider the layout an improvement over the make-up of earlier editions as it

a few have expressed regret that a change in format was made. The bibliographies have been revised, so that articles on which a method is based are listed in chronological order at the end of each section. The index has been revised and enlarged. The book is divided into four parts with two appendices.

Part I includes physical and chemical methods for water analysis. These methods have been arranged independently of the type of water to be analyzed. In the previous edition, an attempt was made to classify the chemical methods for water according to the class of water to be tested. For example, methods for boiler water analysis were given in a separate section. In the 9th Edition, all methods for chemical analysis of water (with the exception of the non-standard methods which still remain in Appendix I) have been consolidated into Part I so that the analyst will find the particular procedure he requires under the appropriate constituent for which the assay is to be made. While this change has been hailed as an improvement by most experienced analysts who are accustomed to the use of Standard Methods procedures it is proving a little confusing to some persons who consult the book only occasionally. The methods for examination of water show many changes and revisions. For example, the test for oxygen consumed has been omitted. The procedures for odor have been completely revised and additional methods have been added for dissolved oxygen, to eliminate interference by other materials. The methods for residual chlorine have been revised in accordance with the recommendations of the Committee on Control of Chlorination of the American Water Works Association. Many new procedures for the detection of various ions have been added, including technics for chromium, phosphates, and fluorine.

In Part II—covering the examination of sewage and sewage effluents—the procedure for dissolved oxygen has been completely modified and the residual chlorine method has been revised to conform with the technique for water. A new diluting water is recommended for the biochemical oxygen demand test. There are several other changes in, and additions to, the various methods.

The text of Part III—relating to the microscopic examination of water, sewage sludge, and bottom sediments—has been revised and expanded to include a more detailed description of the calibration of the microscope and to provide for the reporting of results in standard units.

In Part IV—the section covering the bacteriological examination of water—tryptone-glucose agar has been added as a plating medium, as has lauryl-sulfate-tryptone broth for the coliform test. Fuchsin broth and formate ricinoleate broth have been deleted as media for the confirmed test, although the latter is recommended for special purposes, when spore-forming organisms are found in the completed test. The schematic outlines have been revised, as has the section on coliform density. Bacteriological examination of water from swimming pools is included as a standard, instead of a provisional method. The Eijkman test has been added to the section on differentiation of coliform types.

This section on bacteriological examination of water continues much the same as in previous editions. The group responsible for the present standard procedures have not proceeded blindly upon the assumption that our traditional approach to the bacteriological examination of water should be continued at any cost; but coliform group as an index for judging the effectiveness and the continuity of treatment or the quality of the water as delivered to the consumer. This edition,

however, reflects an open-minded attitude toward continued research and investigation by including once more the scheme for differentiation of coliforms and by incorporating the British methods in an appendix.

Some of the procedures formerly included in Appendix I of the 8th Edition have been transferred to Part I of the 9th as standard procedures. Among these are methods for chloride in low and high chloride waters, for chlorine and for chlorine demand. A few procedures have been deleted from, and a few added to the appendix. Appendix I includes 12 pages of interesting information regarding British practice in the bacteriological examination of water. Extracts from the revised edition of "Bacteriological Examination of Water Supplies," published as Report No. 71,¹ in the British Ministry of Health Series, enhance the value of the 9th Edition and broaden its scope. Appendix II contains a new list of reagent grade chemicals approved by the American Chemical Society, and a new section in which directions are found for preparing the more common laboratory reagents used in water and sewage analysis.

The forthcoming 9th Edition of *Standard Methods for the Examination of Dairy Products* has been prepared jointly by the American Public Health Association and the Association of Official Agricultural Chemists, with assistance from individuals and committees in such organizations as the International Association of Milk Sanitarians and the Dairy Science Association. As has been true of several previous editions, the guiding genius who carried the work to completion, this time under unusual difficulties, was Dr. Robert S. Breed in the capacity, first, of chairman of the Standard Methods Committee on Milk and Dairy Products and, later, as chairman of the Joint Editorial Committee. To his resourcefulness, untiring enthusiasm, and broad knowledge of the whole dairy industry and of the authorities in diversified related fields, the Association is indebted for an edition that far surpasses all of its predecessors. When Dr. Breed would no longer carry on in a dual capacity, Dr. A. H. Robertson was selected for the chairmanship of the committee. Dr. Robertson has brought to this edition an entirely new approach in the presentation of the material and, particularly, a use of the imperative style in the directions to be followed that has eliminated much of the ambiguity of style present in earlier editions. The technician will no longer become bewildered with superfluous discussion and comment when following a scheme of analysis. In the interest of uniformity of arrangement and style in the 9th Edition, the reports by the various referees have been extensively edited to conform to the imperative style of presentation which has been mentioned. The introduction of a simple system of cross-references, and a more satisfactory method of indexing, add greatly to the usefulness of the book. Much duplication and many ambiguities which appeared in the texts of earlier editions have been eliminated in this complete rewriting of the text. Directions clearly reveal whether or not a procedure, or a step in a procedure, is mandatory or optional.

In the 9th Edition of *Standard Methods for the Examination of Dairy Products*, suggestions useful to administrators will be systematically assembled in the first chapter on "Selection and Interpretation of Quality Tests." Credit goes to Luther A. Black for developing this valuable chapter, which briefly describes each test and explains its applications and the limitations of the analyses when the test is used to examine: (1) raw milk and cream intended for pasteurization, (2) pasteurized milk and cream, (3) raw milk and cream to be consumed raw, (4) butter, (5) cheese, (6), frozen dessert ingredients, and (7) frozen desserts. This chapter will enhance the usefulness of the volume to health officers, sanitarians,

operation indicated (26 such operations had been advised on the initial examination and 14 performed; but there was no evidence that these 14 were in better health than the 12 who had not followed this advice). All in all, the children, as a group, were in excellent physical condition; and it would appear that the initial health examination on entrance followed up by annual nurse-teacher conferences, was a definitely satisfactory procedure. If, to the number of children whose defects were brought under care, as a result of the initial examination (47), we add the 3 discovered outside the school, we have a score of 69 per cent on the basis of 50 out of 77 defects corrected. If the initial 1940 examination had been as complete as the 1946 recheck, this figure could have risen to 95 per cent. It would seem clear that a really complete examination at entrance, followed by continuing nurse-teacher supervision, may be an extremely effective procedure.

It should be pointed out that these results were obtained in a population of relatively low economic status but with excellent public medical facilities.

A particularly revealing result of the 1946 study was the very high prevalence of emotional problems of various sorts—in sharp contrast with the favorable findings with respect to physical defects. Disturbing factors in home environment and emotional life were discovered in 44 of the 114 children (39 per cent); and in 10 of these children, the problem was of serious gravity. This is a point on which we lack any general norms of comparison, but it seems clear that this problem requires earnest and constructive consideration. It is probable that in most schools lack of emotional adjustment is quite as important as physical defects and diseases. When more schools follow the example of Astoria, the inadequacy of our community mental hygiene facilities will be revealed in shocking proportions; but we shall only obtain such facilities when the need for them is demonstrated.

The Astoria study is also of great value in demonstrating the intimate relationship of the doctor, the nurse, the teacher, and the parent in a school health program which is really to function. Dr. Yankauer says, on this point "Recent trends of thought in the field of school health have emphasized the fallibility of shaping school medical services solely to prevent and correct physical defects. The importance of educating parent and child to seek early medical assistance, of promoting a positive attitude toward the maintenance of health, and of dispelling inherent fears of doctors and disease by making the examination a desirable educational experience, has been stressed. The presence of the parent and the provision of adequate physician time are essential if this is to be accomplished in the elementary school." We wish he had discussed the influence of the Astoria program on the understanding by the teacher of the health problems of the child in a broad sense. We suspect that coöperation of the sort provided here must go far toward vitalizing and individualizing all classroom instruction.

Finally, this study is of particular significance as illustrating the sort of intensive investigation which is necessary to make the school health program everywhere a really effective instrument of health promotion. Other programs may be as good as the Astoria plan or better. If so, let us have similar careful analysis of the actual health status of the children after exposure to each local program. If a score of health departments would initiate studies of this type, we should really know where we go from here.

NUTRITION AND VITAL RESISTANCE

IT is always exciting when two separate fields of scientific research reveal a point of common contact, so that light from two directions may converge on a single problem.

Such an illuminating convergence was effected in a paper presented by Ames and Nungester¹ at the spring meeting of the Society of American Bacteriologists. These observers worked with the exudative polymorphonuclear leucocytes of guinea pigs and observed their phagocytic activity and their physical stability (in presence of serum) with the addition of varying amounts of ascorbic acid. With concentrations of ascorbic acid of 0.25 mg. per 100 ml. of exudate, only 30 to 35 per cent of the cells showed phagocytosis; with one 1.0 mg. per 100 ml., 80 to 90 per cent of the cells were active. Serum in the system not only promotes phagocytic action, but also protects the phagocytic cells from rupture and destruction. With the low concentration of ascorbic acid, 15 per cent of serum is necessary to obtain this protective action; with the high concentration of ascorbic acid, 5 per cent of serum will do the trick. In the absence of protective serum, 90 to 95 per cent of the cells were ruptured with the low concentration of ascorbic acid; while only 5 to 10 per cent of them were destroyed in the presence of the high concentration.

There is nothing new in the general concept that good nutrition promotes vital resistance. At the same meeting of the S.A.B., Dubos and Pierce reported the marked influence of diet on the susceptibility of mice to experimental tuberculosis infection.² What is new in the studies from Nungester's laboratory at Ann Arbor is the identification of two specific physiological reactions to a specific vitamin. When laboratory techniques, such as these, are devised which will yield precise quantitative results, the investigator is provided with an instrument of research far more powerful than mere clinical observation or even than the procedures of experimental epidemiology.

City Health Department. We have tried to meet the increased cost of living by making an approximate 10 per cent increase in salaries during the past year for all staff positions except division heads. Then again we have increased the vacation period with pay this year from two to three weeks for all employees. Now we are proposing to go on a 40 hour, 5 day work week. This will give employees an opportunity to add to their present salaries by securing additional employment elsewhere over week ends. Nurses can make \$10 for 8 hour duty in our local hospitals, and some of our nurses are already doing this on Saturdays and Sundays.

"In spite of all that we have done, we are losing personnel because of what they consider as inadequate salaries. There is dissatisfaction on the part of many who are still with us. Our present salary range for public health nurses is from \$145 to \$210 per month, the lower salary being paid to beginning nurses with no public health experience or training. However, nurses just out of hospital training are offered \$200 per month for a 40 hour week in one of our local hospitals. We cannot compete with that. One can easily appreciate how a nurse who is paid \$150 per month in this department would find it difficult to make ends meet after having a salary deduction made for income tax plus a 3.5 per cent deduction as a contribution toward the Municipal Retirement Fund. After paying \$10 per week for a room (apartments run much higher), and considering the high cost of food and clothes, there is not much left for insurance, recreation, etc. Certainly a nurse could not buy a car at present prices with such a salary. In fact, we are losing nurses, who are being paid as much as \$185 per month, because they cannot get along on that amount and because they can get much more in doing hospital floor duty.

"The range of salary for our sani-

tarrians varies from \$145 to \$245 per month, depending upon training and experience. This of course does not include the director of the Division of Sanitation who is an engineer. The lowest salary now received by our sanitarians is \$190, while the highest being paid is \$225 per month. One can see that it would be difficult for a man with a family to live under acceptable standards on \$190 per month. All of our sanitarians have outside sources of income to add to their salary which we pay, either by them or by wives working.

"The range of salary for clerks is \$80 to \$150. We pay \$120 as a starting salary to steno-clerks with experience. We are proposing to increase the salaries of all clerks and sanitarians by \$10 per month, the salaries of our laboratory personnel by \$15 per month, and the salaries of all nurses by \$50 per month. The latter will mean that our salaries for nurses will vary from \$195 to \$260 per month. The new nurse with no public health training or experience will receive \$195. However, this is still in competition with the \$200 which she can get doing floor duty in a hospital. Then, too, in a hospital position there is no salary deduction made as a contribution toward a retirement fund. I find that the young nurse would rather have the cash than make the contribution for retirement, although in this city it is matched with an amount equal to twice what she pays and the entire amount draws interest and is paid to an individual leaving our employment.

"I say advisedly that we are proposing these salary increases, for we have no money with which to pay the increases. After all, although our running costs have increased materially, our income or financial support has remained the same. Our department is supported by a one mill tax, plus certain state and federal funds. The latter are being reduced; therefore our only

hope for securing more money with which to pay higher salaries is to secure an increase in tax funds by vote of the citizens. This is a very difficult thing to do. So shall we continue our present staff at present salaries and expect to lose a number of employees, or shall we cut the number of personnel, and cut our program, so as to be able to pay higher salaries? Do you have the right answers? Any help that your 'Clearing House' can give us would be appreciated."

Wilson T. Sowder, M.D., Florida State Health Officer, has sent the Clearing House information about medical officers' salaries in Florida that may be both of interest and value to others. Between September, 1945, and March, 1947, official state and local health departments lost 20 full-time physicians—6 to private practice, 5 to other health agencies, and the remainder for other reasons—unknown, death, and retirement. During the same period it recruited 39 full-time physicians of whom 11 had had no previous public health experience; of the 28 with experience, 9 had had previous experience in Florida and 19 in other states. Only 4 came from other state health departments.

As of March 1, 1947 there were 12 full-time physicians on the staff of the State Health Department and 38 in county health departments. The annual salaries of 11 were \$7,200 or more; 21 received \$6,000 or \$6,600, and 18 received \$5,700 or less. Only 6 were without formal public health training or without experience prior to September, 1945, and of the 6, 2 had had inservice training of 3 months or longer.

In addition Dr. Sowder writes:

"At the moment we have two vacancies for physicians at the state level and one at the local level, but we are losing two excellent health officers within the next few months. We will be opening several new county health departments on July 1, and our total need

for health officers at that time will be about 8.

"So far we have had no difficulty filling positions for sanitary engineers or sanitation personnel but we plan considerable expansion in this field on July 1.

"We share a chronic shortage of nursing personnel along with the rest of the country, amounting to 15 to 20 per cent vacancies. The quality of applicants is not too good. We are also short of laboratory personnel and these positions are hard to fill.

"We are fortunate in Florida in that none of our salaries are limited by statute as is the case in many states and, as a matter of fact, in some state agencies in Florida. Under our law the salaries of county health department personnel are set by the State Health Officer with the approval of the Board of County Commissioners. There is no definitely established procedure for setting the salaries of central office personnel, but it is customary to get the Board's approval for such increases particularly for the higher salaries. When it was decided to set salaries as high as \$8,400, the Board felt it best to discuss the matter with the Governor although this was not required by law.

"Two newspaper stories, one in June, 1946, and the other in January, 1947, indicate that it is sometimes a good policy for a state health officer to pay salaries higher than his own. It seems to have worked very well here twice but I have no plans for trying it again in the immediate future."

William P. Scarlett, M.D., Health Officer, Little Rock, Ark.: "The employees of the Little Rock City Health Department are paid by the state and the city. We operate under a budget set up by the State Health Department according to Merit System Classification. The city matches funds allocated by or through the State Health Department. At the present time the state's

contribution is somewhat greater. Some of our employees are paid entirely by the state, some entirely by the city, and some by both.

"Due to the high cost of living, the city gave a mass increase to all city employees in September, 1946. Those earning \$200 a month or less received a 12 per cent increase, those earning from \$200 to \$300, 7.5 per cent, and those earning more than \$300, 5 per cent. Those paid entirely by the state were not included and those paid in part by the state received an increase only on the wage paid by the city. This caused a lot of ill feeling—e.g., an attendant received a nice increase in salary—more than some of the trained workers received who were being paid by the state and the city. The nurses who receive all their salary from the state received no raise at this time.

"January 1, 1947, the Merit System for State Health Department employees was revised upward a step or so and personnel was classified accordingly. The mass city raise put some of our employees above the Merit System Classification. Those paid entirely by the city have profited, those paid by the state and the city will not receive periodic increases from the state until they have absorbed the increase given by the city. Many of the employees paid entirely by the city cannot meet the minimum qualifications under the Classification plan.

"In December, 1945, we lost an efficient well trained chief nurse because we could not raise her salary. She had been with our department for more than 5 years before going to school to complete her B.S. in Public Health Nursing. She was the first chief nurse of our department and had helped develop our nursing program. At that time \$2,100 was the top salary. She resigned a couple of months after her re-

turn because she felt that she was worth more since she had received her degree. I believe I am correct when I say she had been with the State Health Department seven years before she came to the city. She was paid entirely from state funds after she became Chief Nurse of the City Health Department.

"We are losing an efficient secretary June 1, primarily because her salary has not been adjusted for two years to the Merit System Classification. The state feels the city should add the amount needed and the city stipulates salaries only by ordinance. We will not be able to replace the quality and quantity of work this person does at the salary she receives. She has been with the department 4½ years.

"During the war years we did not have a sanitary engineer. The state budget is set up at \$3,300 for a Senior Sanitarian. Last fall we had the opportunity of employing a well trained sanitary engineer and were successful in getting a city ordinance passed enabling the city to pay \$3,600.

"Last year it was also necessary to start paying a PBX operator two steps up instead of the starting salary, while we have a clerk who has been with the department for more than 5 years and does practically the same work but receives a smaller salary.

"The salary for the director of the local health department is now \$6,000 per annum. The state pays its share, but city ordinance has not been revised to meet the Merit System Classification. I could cite other cases in the department similar to mine.

"The City Comptroller has passed the word for all departments to cut budgets 10 per cent. We are certainly trying to do this without cutting salaries, but there is no way I know of to raise salaries from city funds at the present time."

Credit Lines

ROCKEFELLER FOUNDATION

1946 REPORT

The 1946 annual report of the Rockefeller Foundation (49 West 49th Street, New York) not only reports the number of millions of dollars that went into various fields of human activity—about two and a half million for public health, for the natural sciences, and the social sciences, nearly a million and a half for the medical sciences and the humanities, half a million for restoring the universities of China, a quarter of a million for an agricultural experiment program in Mexico, and smaller sums for equipping research laboratories in France, providing a research faculty in the social sciences at Nuffield College in England, and for research on the organic chemistry of natural products in Switzerland.

Even more, it has some cogent things to say about war's destruction of the human spirit and the "one world" that is a *sine qua non* of scientific progress.

"War not only destroys, it isolates; and isolation means intellectual stagnation. The flow of ideas across boundary lines, the free exchange of periodicals and books, the cross-fertilization of minds working in the same scientific and cultural fields—these are among the tragic losses of war. 'Speech is civilization itself,' says Thomas Mann. 'The word, even the most contradictory word, preserves contact—it is silence which isolates.' This enforced silence has brought losses which are in a sense irreparable—irreparable because they represent lost opportunities and lost time. The list of such losses is all the more formidable because it is blank.

"Invisible on this ghostly list are the beginnings of great new discoveries in genetics, in enzyme chemistry, in nutri-

tion. Perhaps a major entry on the list is the record of what might have been accomplished if all the energy and knowledge and unselfish coöperation which were devoted to making the atomic bomb had been applied instead to some of the great basic problems of biology and medicine."

The entire report will well repay the half hour or so required to read it.

UAW STETHOSCOPE

In May, 1945 (p. 516), Credit Lines summarized briefly Michael M. Davis's *Survey Graphic* article on the opening of the United Automobile Workers Health Institute in the Edsel Ford mansion in Detroit.

In the second year of the operation of the Institute, it began the publication of a monthly publication, *The Stethoscope*. This is a colorful and interesting four page leaflet which gives a good deal of information on health matters and always has at least one amusing illustrative cartoon.

The Institute has three separate services, a medical diagnostic clinic, which diagnoses and refers the patient back to his private physician; health and safety education; and personal service. It is supported by per capita assessments of affiliated locals, the national office of the UAW-CIO and donations from the Detroit Community Chest. Full description of its history and functions will be found in *Public Health Nursing*, for September, 1946, in an article entitled "The Health Institute of the UAW-CIO."

THE CHURCH CONSIDERS ALCOHOLISM

The recent biennial meeting of the Federal Council of Churches of Christ in America adopted a statement of

principles with respect to alcoholism.

"While recognizing the dual origin of alcoholism and excessive drinking in both personal instability and social pressures, and accepting the fact that alcoholism is a disease which requires treatment, the statement of principles reasserts the churches' conviction that the ethical aspects of the use of alcoholic beverages are underlined by concern on behalf of the victims of alcohol."

The Council therefore proposes a long-range, continuing scientific alcohol education program. As to social control of alcoholic beverages, it proposes (1) a revision of the alcoholic beverage tax structure in the direction of encouraging the dilution of proof spirits and fortified wines; (2) strict enforcement of laws regarding issuance of liquor licenses and regulation of hours of sale; (3) prevention of sales to minors; (4) social use of public revenue from the sale of alcohol, namely rehabilitation of alcoholics, relief of their families and repair of other social damages resulting from the use of alcohol; (5) regulation of alcoholic beverage advertising; (6) local option, namely freedom of neighborhood, community, or state to bar traffic in alcoholic beverages if a majority of the citizens agree upon such action; (7) indirect control of alcoholic consumption by the control of contributing factors, such as poor housing, inadequate recreation facilities, and broken homes, as well as through the transforming power of the Christian Gospel.

BIOGRAPHY OF DR. HURTY OF INDIANA

Dr. Thurman B. Rice, of the University of Indiana Medical School, and former Indiana State Health Officer, has just sent out the 96th and last chapter of his biography of John Newell Hurty, M.D. Begun as a serial in the January, 1939, *Bulletin of the Indiana State Board of Health*, the last chapter appeared in the issue of December, 1946.

It is a detailed, chatty, complimentary, and profusely illustrated biography written as a labor of love by Dr. Rice, who received his public health training and inspiration under Indiana's first and perhaps most famous state health officer.

The reprints of the biography, which Dr. Rice proudly says approximately equals in length Boswell's unabridged *Life of Johnson*, will be widely distributed among Indiana's schools, colleges, and libraries, as well as among the more important libraries and universities of the nation. One hundred copies are being reserved for foreign libraries. Dr. Rice has insured that posterity shall not forget John Newell Hurty, the Hoosier Health Officer.

LEPROSY IN VARIOUS PARTS OF THE WORLD

In March (p. 1313), *Credit Lines* brought you up-to-date on what is being planned for the National Leprosarium at Carville, Louisiana. Now comes the *March News Letter* of the Health and Sanitation Division of the Institute of Inter-American Affairs. It tells the story of "Santa Isabel," Paraguay's leper colony, where in September, 1946, a hospital and water supply system constructed by the Inter-American Cooperative Service for Public Health were turned over to the Paraguayan government. Generously illustrated with photographs this article describes Paraguay's leper facilities fully pointing out how the experience of the Louisiana institution has been used. Special emphasis has been placed on the preventorium for children born of parents with leprosy.

The same article describes Brazil's 26 preventoria briefly. These grew out of a layman's movement started by Mrs. Eunice Weaver in 1930.

Also at hand is the Easter and initial issue of the *Leprosy Digest*, published by the American Mission to

Lepers. This summarizes some of the activities being carried on by this church group in various parts of the world—China, Africa's Gold Coast, the Belgian Congo, and many others. It also has a lovely Easter legend of the dog-wood and how it came to be. Published at Suite 1017, 156 Fifth Avenue, New York 10.

RECOMMENDED CHANGES IN ENGINEERING CURRICULA

The American Engineer, March, 1947, publication of the National Society of Professional Engineers, carries an account of the report of the society's Committee on Education presented at the Annual Meeting in Atlanta on December 8, 1946.

Of particular interest to all engineers is the recommendation that all basic engineering courses be extended to five years to enable qualification for an engineering degree. A further recommendation is to the effect that 20 per cent of the credits in any course of engineering be acquired in the study of literature, English, writing, public speaking, economics, business administration, history, U. S. Government and its advantages, sociology, psychology and contract law. They continued their recommendations with the following: "That the National Society of Professional Engineers give prompt consideration to ways and means to expand the proposed five year minimum into a minimum six year program as soon as that can be accomplished. We realize that this will take time."

"DISASTER" WOULD PREVENT DISASTER

March, 1947, saw the birth of *Disaster*, a monthly publication of the Red Cross devoted to the broad field of disaster relief and prevention. "Disaster prevention must begin in the minds of man. To provide the facts needed to blast fatal it-can't-happen-here attitudes, this publication will

report month by month news of disasters in the nation," declares the first issue.

Cover pages of the first two issues are a Currier Ives reprint of the great Chicago fire and John Stewart Curry's "The Mississippi" (in flood). It is designed to inform not only chapter directors of disaster relief but the general public as well.

RAILROADS AND TYPHOID FEVER

In 1903 an article entitled, "An Unappreciated Source of Typhoid Infection," by Dr. Paul B. Barringer, dwelt on the possible danger that existed along railroad right of ways, due to improper disposal of human excreta from railway conveyances. Dr. Barringer visualized this danger as real and grave. He considered the possible spread of typhoid through this condition by: (1) drinking water infected by the excrement from passing cars or washed from the roadbeds of railways; (2) infection to persons handling contaminated ties, earth, and dust of the roadbed, and (3) infection caused by constant exposure to the clouds of dust raised by passing trains. Over the years this theory has had widespread acceptance, although definitive proof has been lacking.

One of the early projects undertaken through the newly organized Sanitation Research Project of the Association of American Railroads (*A.J.P.H.* 37, 3:345) was the investigation of this theory and of means for a better disposal of sewage waste. A report dated November 8, 1946, and submitted by Kenneth E. Maxcy, M.D., entitled "An Inquiry Into the Public Health Hazard of Sewage Disposal from Railway Conveyances," gives the results of the investigation. An exhaustive search of the literature, United States and European, failed to substantiate the theories advanced, according to Dr. Maxcy. An extensive list of references is included.

RESEARCH ON FROZEN PRECOOKED FOODS

A recent article, "Microbiological Aspects of Frozen Precooked Foods," by B. E. Proctor and A. W. Phillips, Jr., appearing in the January, 1947 issue of *Refrigerating Engineering*, outlines certain experimental work done by the two authors in an effort to determine possible hazards to health that might exist in frozen precooked foods due to biological contamination.

The results of their study, as listed under their summary, indicate that "not all frozen precooked food products being manufactured and sold today are subject to either constant or strict bacteriological control." They find a need for bacteriological control of such foods and they point out the importance of extreme care in all the manufacturing operations combined with immediate freezing and continued storage at below zero temperatures until the food is ready to be prepared for consumption by the ultimate consumer. They also advocate some method of coding packages with the date of preparation and the packager.

DO YOU HAVE A GARAGSMAN FRIEND?

If so, you'll be interested in the booklet, *Prevention of Health Hazards in Repair Garages*, published by the Departments of Labor and Industries and of Health of the State of Washington. Even if you do not have a friend in the garage business you should be interested in this illustrated discussion of the dangers present in repair garages due to carbon monoxide, paint sprays, faulty illumination, fire hazards, etc. What is more, you should know the preventive measures listed in the booklet.

FEDERAL AND STATE STANDARDS FOR MILK PRODUCTS

The Bureau of Dairy Industry, Agricultural Research Administration, U. S. Department of Agriculture, recently published a compilation of data that

should be of interest to many health workers. The title of the report is "Federal and State Standards for the Composition of Milk Products." It was published in February, 1947, and bears the code number BDIM-Inf-45.

Under appropriate headings it shows the federal and individual state standards for various milk constituents and products, such as whole milk, skim milk, ice cream, cheddar cheese, etc.

ROTARY'S CANCER QUIZ

The April, 1947, *Rotarian*, the organ of the Rotary Clubs of America, has a Quiz on Cancer. Prepared in collaboration with the American Medical Association, it has the answers to questions most commonly asked. It is an excellent presentation for the lay reader and should be useful in spreading correct information about this much feared and little understood disease.

HEALTH HORIZON

The British National Association for the Prevention of Tuberculosis has forwarded the January issue of *Health Horizon*. This quarterly devoted to health education is now in its second year. By 1948 it hopes to be a bimonthly. It is a bright, informative, small magazine of some sixty pages that belies England's current austerity. Its January prescription for health is, "Take this magazine four times a year, dilute it with your commonsense, read it before meals and after meals—and you will know more about yourself, and therefore be healthier."

MISSOURI RECOMMENDS COUNTY HEALTH UNITS

By way of educating the citizenry of the state, John W. Williams, M.D., the Director of Local Health Administration in the Missouri State Health Department, has prepared a pamphlet entitled "You Can Have One." With a picture of the attractive Neosho-Newton

County Public Health Center on the cover, it asks and answers some 20 questions about what county health units are and how a community may have one. It gives simple instructions as to how cities and counties can coöperate in setting up a health department, and how several counties may join in forming a health district as provided by recent legislation in Missouri.

CANCER NEWS IS NEW

Granville W. Larimore, M.D., director of the American Cancer Society's Education Department, sends us the first two issues of *Cancer News*. Beginning in January, 1947, this replaces the Society's *Field Army News* which was first published in 1942. The *News* is planned to become an educational journal on cancer for the interested layman. It is a very attractive magazine on good paper with excellent photography and graphic illustrations.

THE STATE OF COUNTY HEALTH SERVICES IN OREGON

In three recent issues of the weekly *Oregon Health Bulletin*, Oregon citizens are made acquainted with their county health services. Using Dr. Emerson's *Local Health Units for the Nation* as a springboard, Dr. Richard H. Wilcox, Director of the Division of County Health Units, tells why counties are without organized service and why theoretically organized counties are without personnel. Consolidation of counties for currently unserved areas and higher salaries to workers in organized counties are his two chief prescriptions. He does a very good job of outlining the Oregon situation in the background of the national situation and also of relating his discussion to the proposed health unit bill under consideration by the Oregon legislature. The series is well written and manages somehow to convey the idea that the author is taking the citizens into his

confidence rather than admonishing them. His definition of health departments is worth repeating, "packaged units of professionally trained men and women who are charged with the duties of rendering a half dozen essential primary services of public health to the people."

WORTH ACQUIRING

Tuberculosis Basic Facts in Basic English is a new edition of a popular National Tuberculosis Association booklet designed to help the physician, nurse, and social worker explain tuberculosis to a patient and the family. Available from state and local tuberculosis associations.

Guide to Health Organization in the United States—To meet the need for a ready reference guide to health organization in the United States, Joseph W. Mountin, M.D., and Evelyn Flook have prepared this pamphlet published by the U. S. Public Health Service. It brings together in brief and simple form the salient functions of the many agencies that render health services in the country. The respective contributions to public health of federal, state, and local official and voluntary agencies and of private physicians, dentists, nurses, and sanitary engineers are clearly defined. The result is a panoramic view of the health structure of the nation. It should be of help in orienting professional public health workers as well as American students and visitors from other countries. U. S. Govt. Ptg. Office, Washington 25, price 20 cents.

For You and Yours is prepared by the Federal Security Agency to tell citizen Joe how the agency touches his life and that of his family, including the aged and the handicapped. There is a very good double page chart that relates all federal services to the local community agency, school health depart-

ment, welfare department, etc., which is the point of contact for these services in which, it is said, the federal agency carries its share of the partnership. Also it has a list of dates when the various Federal Security Services began, the earliest being the Public Health Service in 1798. Appears to be available without charge from the Federal Security Agency, Washington 25, D. C.

How to Live Longer—A restful looking blue and white pamphlet by Liberty Mutual Insurance Co. (Boston), on the dozens of ways to prevent accidents in the home. Reminding the reader that he is 100 times more likely to be hurt than killed, it describes, and illustrates the kitchen, the "hot spot" of the home for burns, scalds, explosions. Stairway hazards, bad labeling in medicine closets, junky cellars and attics are all rounded up. Finally it is suggested that you be your own safety expert, going through

each room and finding and eliminating the booby traps. Most accidents have two causes, the physical circumstances and a mental lapse.

WORTH QUOTING

Speaking of the \$1,000,000,000 needed for relief in Greece, Turkey, and Korea, Jennings Perry in *PM* of March 26 declared, "The way to grasp an unknown quantity, of course, is to relate it to something that is known. For instance 1 billion is just 1/262 of the national debt, and obviously, looked at that way, not such a much. On the other hand, it would buy us at home complete TVA-model control of (1) the Ohio, (2) the St. Lawrence, or (3) the Arkansas. It would build, equip and endow us modern hospitals in 1,000 American towns. It would wipe out venereal diseases, smallpox, typhoid, and maybe cancer. And looked at that way it is right considerable."

University of North Carolina

The Department of Public Health Nursing, School of Public Health, University of North Carolina, announces a change in the curriculum leading to a certificate in Public Health Nursing.

Beginning September, 1947, the curriculum will consist of three-quarters academic work, plus one-quarter field work.

In addition to the certificate program, the School of Public Health offers a Bachelor of Science degree in Public Health Nursing.

The School of Public Health also offers an M.P.H., or a Master's degree may be obtained in Sociology or Education.

BOOKS AND REPORTS

reviews are prepared on invitation. Unsolicited reviews cannot be accepted. books reviewed in these columns may be purchased through the Book Service.

Adjustment to Physical Handicap and Illness: A Survey of the Social Psychology of Physique and Disability—By Roger G. Barker, Beatrice Wright and Mollie R. Gonick. New York: Social Science Research Council, 1946. 372 pp. Price, \$2.00.

The title of this book does not prepare one for the wealth of material contained between its covers. The insight of the authors in dealing with the psychosomatic approach to many problems the handicapped should make this a valuable reference for the medical and allied professions regardless of each one's special interest.

The book abounds in interesting reports of study and control groups used in this study. A few examples are: the handicaps of slight normal variations such as obesity or extremes in height; our personal reactions and how they come about; our nicknames, jokes, fiction and drama as they give us narcissistic satisfaction or fear. The influence of physique upon behavior and behavior upon physique are studied in providing background for consideration of the more specific problems of the disabled veterans and other civilians who must accept their handicaps and adjust them to our society. Problems of those with orthopedic and other physical disabilities are analyzed, as well as those of the acutely ill. We of the professional field are apart from the patient who enters on a terra incognita to him. He is insecure, unstable, and dependent upon us. We in turn may easily turn him to infantilism in his reactions because of circumstances beyond his personal control.

The authors have applied their psychology to the extent that the book is written in such a manner as to have the reader easily identify himself and those about him. In no way do the authors spoon-feed the reader. However the book demands a thoughtful approach to the hypothesis presented, both because of the vague nature of our social concepts and because of the presence of the human equation in the behavior of disabled people.

A final chapter deals with rehabilitation and employment of the handicapped, giving the application of principles learned in the war years. The approach is from the point of the patient as he meets the common problems of today. .

The book is well organized and comprehensive, yet written in an interesting style, and completely indexed. The extensive bibliography is most inclusive.

MARGARET P. LADD

The Compleat Pediatrician—By Wilbur C. Davison, M.D. (5th ed.), 1946, unpagged (256 numbered items). Price, \$3.75.

This perennial favorite has gained strength in the war years. It boasts of changing 10,000 lines in this edition, and now stands alone on its own feet with almost no references. Discussions on chemotherapy and infectious and tropical diseases have been greatly expanded. It is still probably useful chiefly to those physicians who are as well versed in pediatrics as the author and who admit, as he does, that the book should "jog his memory on possibilities, but it cannot do his thinking for him." Actually

the volume can be used only by those who are sufficiently earnest to find out how to use it. It is not to be read consecutively but is a cross-referenced handbook.

The public health expert will be pleased at the amount of information on prevention of disease and on growth and development of normal children. He should perhaps be concerned that the author apparently does not read this *Journal*. In its columns the reviewer of the fourth edition called attention to the sentence, "Sex: The ratio of males to females at birth is 1,043 to 1,000, and is higher in rural areas, immediately after wars and in Greece." It remains unchanged in this fifth edition. But that is no reason to scorn a thin pocket book which answers most of the questions those who deal with preventive and curative medicine for children may have.

LEONA BAUMGARTNER

Health Insurance in the United States—By Nathan Sinai, Dr.P.H. New York: The Commonwealth Fund, 1946. 115 pp. Price, \$1.50.

Another in the outstanding series of monographs under the aegis of the New York Academy of Medicine, this is an able discussion by an able authority and his associates. Its seven chapters carry the reader through a well organized sight-seeing tour of the evolution of the health insurance movement, both hospital and medical, in this country.

In common with all good conductors of tours, at least one of the authors has interspersed touches of his own adroit philosophy. These are interesting and worth while both in commission and omission but their presence should not be lost upon the objective reader.

This is a most valuable book. But so rapidly has this problem been advancing that need for a revised edition can already be seen. A series of supplemental articles is suggested pending

such. We hope the authors will perform this service.

EDWARD S. ROGERS

A Blind Hog's Acorns—By Carey P. McCord, M.D. Chicago: Cloud, Inc., 1945. 311 pp.

Any book explaining and popularizing public health is of special value in these days of shortage of public health personnel. Carey P. McCord dramatizes and enlivens the industrial health field in a series of charming stories, reflecting the vast importance of this field, while entrancing his reader with the art of the true raconteur, an art which his friends have long enjoyed when with him on field trips, at the luncheon table, and at meetings. This little biographical book brings the industrial preventive medicine story to the public with an effectiveness that ranks with *An American Doctor's Odyssey*, *Plague on Us*, and *Yellow Jack*.

The puzzling title is quickly explained in the first pages and becomes uniquely apropos when we learn that the author's childhood was warped by the edict of an itinerant phrenologist, who pronounced his "bumps all wrong—his head proves he just ain't fitten," whereupon his father decided he was still worth rearing since "even a blind hog gets an acorn once in a while." Thereafter the book contains such a surprising collection of tasty acorns of wit and wisdom, as to leave no question of the father's sound judgment.

As might be expected of one of his erudition, the author, try as he will to avoid it, lapses into technical language occasionally, having expressed himself thusly all these years. But the terms are easily understood and are used in a way which flatters the non-medical reader's intelligence. His basic tenet, that "a little piece of man" goes into every job performed by man, and that this constitutes a day-by-day process of attrition of body and mind, is well illustrated, and

becomes the basis of the industrial hygienist's creed: to reduce that process to a minimum. His pursuit of the "chiclero's disease" in the jungle of Central America and finding it to be leishmaniasis, the "four o'clock mystery" when all workers in a large office became ill at four each day, his many experiences with the legal fraternity, his investigations of lead and dust hazards, and many other important contributions made to the young science of industrial hygiene are woven into nicely connected stories told with modesty, humor even at his own expense, and a rare piquancy. The illustrations by Strobel add much to the humor and style. This is good recreational as well as philosophical reading for anyone.

W. P. SHEPARD

Practical Physiological Chemistry
—By Philip B. Hawk, Ph.D., Bernard L. Oser, Ph.D., and William H. Summer-
son, Ph.D. (12th ed.) Philadelphia:
Blakiston, 1947. 1,323 pp. Price,
\$10.00.

Biochemists and many others will welcome the new edition of this classic. Something of the growth of the science is indicated by the increasing size of the work; the 8th edition (1923) contained 693 pages; the present edition contains 1,323 pages and employs a smaller type size. The various sections of the book have either been completely rewritten or revised by the addition of new material. The following are among the new procedures and methods included in this edition: electrophoresis patterns of blood plasma; spectrophotometry, flame photometry, and photofluorometry, including the theory and use of nearly all of the instruments now in common use (Evelyn, Beckman, Pfaltz, and Bauer, etc.); assay methods for the vitamins, including bioassay, microbiological assays, chemical, and fluorometric.

For two decades this reviewer has

been looking for a laboratory manual in biochemistry which was compiled with consideration given to simplicity and uniformity of reagents required. This is not the book. For example, the laboratory procedures given in the first 400 pages require no less than 28 *different* concentrations of HCl.

As was true of the former editions, the new Hawk will be widely used by teachers of biochemistry, but it will be no less useful to physicians, medical biochemists, and technologists, physiologists, and investigators in biochemistry. Many will find it indispensable.

PAUL L. DAY

International Health Conference, New York, N. Y., June 19–July 22, 1946. Report of the United States Delegation, including the Final Act and Related Documents. Washington: U. S. Gov. Ptg. Office, 1947. 145 pp. Price, \$35.

The report of Dr. Thomas Parran as Chairman of the United States Delegation to the International Health Conference of 1946 has been published by the U. S. Department of State, and is a document which should be widely distributed in libraries in order that the Constitution of the World Health Organization and something of its procedure and the interim arrangements which have been made following the Conference should be widely understood.

REGINALD M. ATWATER

Layout, Building Designs and Equipment for Y.M.C.A. Camps—Prepared under direction of John A. Ledlie. Building & Furnishing Service National Board, Y.M.C.A. New York: Association Press, 1946. 48 pp. Price, \$3.00.

This is an attractively printed brochure prepared to suggest components for a Y.M.C.A. camp with a capacity of 125. Floor plans give room arrangements and crude dimensions. Archi-

pects' sketches illustrate most buildings discussed. The purpose of the brochure is to depict an ideal plan which could be reduced as funds necessitated. There is a good general discussion of the need for proper sewage disposal and the typical parts of a satisfactory disposal system, although many will disagree with some of the operative characteristics given. This discussion is quite general; it does not give detail for any phase of camp construction or operation.

FRANCIS B. ELDER

Survey Report of the Salary Standardization Board. *Albany: New York State Civil Service Department.* 301 pp. Price, \$1.50.

The first finding of this report is: "In the main, gross salaries presently paid (including emergency compensation), are comparable with and in proper relationship to salaries paid in private industry and in other public jurisdictions," and the recommendation is: "The present emergency compensation should be made permanent and incorporated into the basic salary structure."

In the schedules used for the past decade, 13 occupational services were provided, with 194 salary grades. This report recommends a general schedule of 50 grades with no divisions into services, in which the lowest salary begins at \$1,500 and rises to a maximum of \$2,100 at the sixth year. The highest for which increments are stated begins at \$10,500 with a maximum of \$12,500. Decisions as to how workers in certain fields will fit into the general schedule of Grades 1 to 50 will be completed by October 1, 1947. The report states: "Estimates made show that the added adjustments necessary to convert the present gross salaries to the proposed salaries will average slightly over \$50 per employee, and will cost the state about 2.5 million dollars." Although 52,500 is frequently used as the number

of state employees, a frequency table of only 39,337 salaries is given. This table affords a median of \$2,319. The average salary is stated to be \$2,448. Thus, the additional 2.5 million dollars is an increase of almost 3 per cent for the total payroll.

Average salaries for accountants, librarians, personnel administrators, and public health nurses employed by the federal government appear distressingly high to the New York State Board. The graphs comparing salaries in various fields in private industries, federal government, other states, and New York State are interesting.

Job descriptions occupy 213 pages, and some titles will be described later. Among those of interest to readers of the *American Journal of Public Health* are physical therapy technician, physician (institutional work), public health nurse, senior psychiatrist, social worker, statistician, stenographer.

Personnel practices in other areas of employment were found to be, with one exception, more liberal for New York State employees. The policy about overtime pay was the exception.

A very interesting table to the 52,500 employees of the State of New York will be the one which shows to what proposed grades their present grades will be transferred.

DOROTHY E. WIESNER

If You Ask My Advice—By Henry Pleasants, Jr., M.D. *Boston: Bruce Humphries, Inc., 1946.* 110 pp. Price, \$2.00.

The author presents a "brief and somewhat informal essay" on a number of general popular topics, such as insanity, alcoholism, drug addiction, sex, child and family problems, etc. The style is sketchy and anecdotal and the treatment is so superficial that one feels little has been accomplished. Dr. Pleasants has had a diversified medical experience and has written several

books, one of which was a Book-of-the-Month selection. Excellent writing ability is evidenced in this small booklet, but the quality and quantity are insufficient to satisfy the reader with the advice given.

CHARLES E. SHEPARD

What Do You Know About Blindness? By Herbert Yahraes, *Public Affairs Pamphlet No. 124. New York: Public Affairs Committee, 1947. 32 pp. Price, \$.10.*

The public health worker will want to have at least the minimum information that is in this well written pamphlet about a condition which affects one in 600 Americans, whether or not he has a friend who is blind. Discussion of causes and prevention is condensed to a few pages, but in general this provides a good summary.

The statement that "... school work is bound to make worse ..." uncorrected defects of vision is based on coincidence rather than scientific evidence. It is true that myopia, for example, is greater in the older grades; many ophthalmologists feel that this comes about from natural growth processes rather than from the conditions under which eyes are used. More light is needed on this and other problems. On the other hand, there are certain less common eye conditions, such as high myopia, in which special educational adjustments based upon medical recommendations definitely are indicated.

FRANKLIN M. FOOTE

Tuberculosis in the United States. Prepared by Field Studies Section of the Tuberculosis Control Division of the U.S.P.H.S. New York: National Tuberculosis Association, 1946. 189 pp.

Volume 4 of the series titled "Tuberculosis in the United States" was preceded by one volume annually since 1943. The first three volumes covered mortality statistics and proportionate

mortality statistics for states and geographical divisions, and mortality statistics for cities of 100,000 or more population—all by age, sex, and race.

The present volume covers mortality statistics in a similar manner for smaller population groups. The graphic presentation gives a bird's-eye view of the data so that "he who runs may read."

Inasmuch as the figures pertain to the status existing from 1939 through 1941 they are not new.

A striking fact is that while in the white population the death rate in urban places was not much greater than in rural areas (38.1 as compared with 35.1), the rate for non-whites in urban places was 72 per cent greater than in rural areas (169.8 as compared with 98.3).

JOHN H. KORNS

Tutoring as Therapy—By Grace Arthur, Ph.D. New York: The Commonwealth Fund, 1946. 125 pp. Price, \$1.50.

On the central theme of the child's necessity to be able to compete on equal terms with others of his group, Dr. Arthur presents, in a smoothly integrated blend of exposition and case history, some of the obstacles to group learning which render children insecure and the methods by which tutoring can overcome these obstacles.

Drawn largely from a tutoring project set up during the depression, the material illustrates the usefulness of tutoring in school failures resulting from illness, home maladjustments, inferior mental equipment, physical incapacities, intellectual idiosyncracies, and special disabilities.

Consideration is given to the qualifications of tutors, to family and community coöperation, and to the limitations of the method. Special emphasis is laid upon the rôle of the psychologist as mentor and guide.

Of interest primarily to teachers and psychologists, this small readable book

is provocative and enlightening to all workers in the field of family health, partly by reason of its indirect reëmpphasis on the values of agency coöperation. MARGARET E. MAHIN

Your Community—By Joanna C. Colcord. A revision by Donald S. Howard. New York: Russell Sage Foundation, 1947. 263 pp. Price, \$1.50.

The revision of *Your Community* by Joanna Colcord brings to date a valuable publication to the public health field.

Health education workers recognize that man does not live to himself alone and that his health problems are involved in the social problems of his environment. Miss Colcord's book gives a mechanism through which persons may become aware of community problems and their relationships. It is valuable for study groups who wish to make a contribution to the welfare of their communities.

The chapters dealing with health and medical care have been expanded, and that on housing, planning, and zoning offers some thought-provoking questions to public health workers.

The book is of value to students in schools of public health as well as to workers in the field. The Russell Sage Foundation has done well to present this revision by Donald S. Howard.

MARY P. CONNOLLY

The Modern Attack on Tuberculosis — By Henry D. Chadwick, M.D., and Alton S. Pope, M.D. New York: The Commonwealth Fund, 1946. 123 pp. Price, \$1.00.

This outline-manual covers its subject briefly and should interest all health officers and administrators charged with the planning of tuberculosis

control programs. It has both an index and a bibliography.

The authors outline programs for a tuberculosis control division in a state health department and for county and city departments. They regard as essentials in such programs (1) coöperative medical profession, (2) readily available x-ray and laboratory service, (3) well run tuberculosis hospitals, (4) case register and public health nursing service in the health department, (5) a director qualified in both general public health and tuberculosis. They emphasize the continuing need for consultation clinics of high caliber, intensive follow-up of patients and suspects, mobile clinics with x-ray equipment, and more x-ray examination of mature and elderly adults (particularly men).

This should prove a valuable reference book for physicians and nurses engaged in tuberculosis control.

ALAN L. HART

Nursing for Community Health—By Theda L. Waterman, R.N. (2nd ed.) Philadelphia: Davis, 1947. 421 pp. Price, \$3.50.

The second edition of Miss Waterman's book presents fresh bibliographical, illustrative, and text material for the use of students in schools of nursing. As the author herself states, the program of public health is both simple and complex, and to select that which is most important to give the student a broader understanding of community health is not easy. The author has chosen the fields of community service commonly covered by public health nurses and describes briefly the agencies concerned therein. The bibliographies are generous and part II offers a teaching and study outline which will be helpful to instructors.

DOROTHY DEMING

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Not One But Five Dollars Needed
—On a budget of about a dollar a day per patient, mental hospitals (public) are expected to provide board, room, clothing, entertainment, medications, and high-grade medical and nursing care. That is one measure of our reluctance to face realistically the pressing psychiatric problems of our day.

ANGUS, L. R. The Challenge of Psychiatry in 1947. *Canad. Pub. Health J.* 38, 4:157 (Apr.), 1947.

Good News for You as Citizen or Sanitarian — Experience with DDT spraying of dairies, restaurants, and small food shops leads to the conclusion that effective control of houseflies may now be achieved by an individual, a business, or a community.

BAKER, W. C., *et al.* The Control of Houseflies by DDT Sprays. *Pub. Health Rep.* 62, 17:597 (Apr. 25), 1947.

Sans Billingsgate—Do make an effort to hunt this one out! It describes the revolutionary changes about to take place in British medical, hospital and health services. The whole tone of the letter is good natured, fair, and frank. When, do you suppose, will we achieve the adult ability to discuss controversial issues unemotionally?

BROCKINGTON, F. Letter from Great Britain. *Canad. Pub. Health J.* 38, 4:207 (Apr.), 1947.

Entre Nous—Just what governs the choice of items annotated here? Please don't answer, the Lord only knows! One qualification is that the item appear in one of the scientific or professional periodicals reasonably accessible to health people generally. Another is that it be of some interest, presumably, to a large number of our *Journal's* readers. This little excursion is prompted

by my decision not to comment on a paper on vaccine manufacture which, I suppose, is of practical moment to not more than ten readers, and to them, it is of such immediate importance that they will know all about it. (Also this confession saves me the trouble of reading it.)

DUCOR, D. H. An Improved Method of Producing Smallpox Vaccine of Low Bacterial Content. *Pub. Health Rep.* 62, 16:565 (Apr. 18), 1947.

Contrary to General Pediatric Opinion—For premies, cows milk properly modified will produce greater gains in weight than human milk, say these researchers.

GORDON, H. H., *et al.* Feeding Premature Infants. *Am. J. Dis. Child.* 73, 4:442 (Apr.), 1947.

To Be Tucked Away—Another report that penicillin-treated scarlet fever patients had fewer complications than those treated with convalescent serum or sulfonamide drugs.

HOYNE, A. L., and BROWN, R. H. Penicillin for Scarlet Fever. *Med. Officer.* 77, 15:143 (Apr. 12), 1947.

Penalties of Progress—New methods of treatment for gonorrhea and syphilis have brought almost as many problems as blessings. This challenging introduction to a paper you will want not to miss should be enough to send you to it. You'll profit by the paper that follows it, too, once you get started.

INGRAHAM, N. J., JR. Treatment Progress in Venereal Disease Control (and) PICKENS, M. E. The Nursing in a Changing Venereal Disease Program. *Pub. Health Nurs.* 39, 5:250 (May), 1947.

Five-Year Health Plans—Among other things that the Russian health

authorities are attempting, is routine administration of BCG to all new-born. Adults under special risk are given the protection, too.

MUDD, S. Programs for Medicine and National Health in the USSR. *Science* 105, 2724:269 (and) 105, 2725:306 (Mar. 21), 1947.

Paper-of-the-Month — That much discussed report upon the possibilities of bacterial warfare is here. Being in the line of business you are, you will want to be able to say "Yes, I've read it." You can get a reprint by sending one dollar to the publisher (Williams and Wilkins). Perhaps you should be warned that the paper is of a pre-war vintage and is based upon data published prior to 1942. There is nothing in it about secret research conducted since that time by the military.

ROSEBURY, T., and KABAT, E. A. Bacterial Warfare. *J Immunol.* 56, 1:7 (May), 1947.

Excuse This Please—This is, of course, of professional interest only to you, but you will be glad to know that DDT kills cockroaches and bedbugs too.

STENBURG, R. L. The Techniques of Application and the Control of Roaches and Bedbugs with DDT. *Pub. Health Rep.* 62, 19:669 (May 9), 1947.

For Pleasure First, Then Profit—Here is that rarity in the scientific press, an amusing though profound dissertation. One sentence: "To be sure we do have encyclopedic consultants, who on the push of a button spout Information

Please or what might be degraded by the designation 'info'."

STOKES, J. H. What Is a Consultant? *Pub. Health Nurs.* 39, 5:239 (May), 1947.

Five Ways to Reduce Measles Morbidity—If you are looking for a brief, well organized, practical statement about what's new with measles prevention, and treatment, then you'll find it here. Nothing sensational, to be sure, but a good workman-like review.

TOWSLEY, H. A. Measles. *Am. J. Nurs.* 47, 5:278 (May), 1947.

Department of High Aims—Within 5 years, if all resources are mobilized, a complete picture of tuberculosis in the United States can be obtained. The goals of the USPHS are the discovery of all tuberculous persons, medical care of every patient needing treatment, after-care and rehabilitation, and protection of families against economic distress. This paper is about the mechanics of reaching the first goal.

WEBER, F. J. Community-wide Chest X-Ray Surveys. *Pub. Health Rep.* 62, 18:652 (May 2), 1947.

Epidemiologic Note — Penicillin shortens markedly the duration of the convalescent and chronic carrier states if given in sufficient quantity to patients with diphtheria. The drug has no beneficial effect upon the clinical course of the disease, reports this researcher.

WEINSTEIN, L. The Treatment of Acute Diphtheria and the Chronic Carrier State with Penicillin. *Am. J. M. Sc.* 213, 3:308 (Mar.), 1947.

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

- THE ACUTE INFECTIOUS FEVERS. By Alexander Joe, D.S.C. Philadelphia: Blakiston, 1947. 276 pp. 64 illus. Price, \$4.50.

ASSOCIATION NEWS

AN ASSOCIATION COÖRDINATING COMMITTEE ON LABORATORY METHODS

The American Public Health Association has been a pioneer in establishing standards for laboratory work. Even before the Laboratory Section was founded in 1899, committees of the Association were active in studying Laboratory methods and recommending uniform procedures. Six reports preceded publication of the first edition of *Standard Methods of Water Analysis* in 1905. The committee appointed to study bacteriological methods for milk published the first edition of *Standard Methods for the Bacteriological Examination of Milk* in 1910.

Until the year 1920, such work was carried on independently by various committees of the Laboratory Section. At that time it was decided that more coherent work could be accomplished if these committees were consolidated into a single Standard Methods Committee. Such a committee was formed early in 1921 and under its leadership the methods for both water and milk carried through several editions.

As the interests of the Section expanded and it seemed desirable to provide uniform methods for a wide variety of laboratory examinations, it became apparent that no single committee could be representative of all the special fields involved, so in 1933 the standard methods machinery of the Laboratory Section was revised and a number of independent committees on laboratory methods were again set up. At this time the chairmen of these various committees were appointed to a new Coördinating Committee on Standard Methods, whose function was

to stimulate and coördinate the work of the several committees. Under this organization, the first two editions of *Diagnostic Procedures and Reagents* were published, the new volume on "Laboratory Procedures in Virus Diseases" is being prepared, *Standard Methods for the Examination of Dairy Products* was enlarged to include frozen desserts and ingredients, *Recommended Methods of Procedure for Bacteriological Examination of Shellfish and Shellfish Waters* was issued, and the A.P.H.A. responsibility for *Standard Methods for the Examination of Water and Sewage* carried through two editions.

Up to this point these committees have been organically a part of the Laboratory Section structure, although from time to time representatives of other Sections have been invited to serve on them. However, during the past few years, there has been an increasing expansion of interest in laboratory methods throughout the Association, extending far beyond the Laboratory Section. It is becoming increasingly evident that two groups of workers are interested in any laboratory method, a group actually performing the laboratory examinations and an equally important group applying the results of these examinations to field conditions and interpreting such application. The persons primarily interested in certain problems such as those of food technology are members of other Sections of the Association, even though these problems involve primarily laboratory procedures. This has led to a desire on

the part of several of the Sections of the Association to have a formal share in the preparation of laboratory methods, not only as technical procedures within a laboratory but also in the interpretation and application of laboratory results.

Recognizing the broad Association interests in all laboratory methods, the Committee on Research and Standards at the November, 1946, meeting in Cleveland appointed a special committee to consider the Association's present needs and to explore ways and means by which a coordinating committee could be formed to represent all those Sections of the Association which have an interest in laboratory procedures and their application. This committee was also instructed to investigate ways by which the time elapsing between the actual preparation of methods and their publication could be reduced from that

necessitated by existing requirements.

John F. Norton, Ph.D., and Reginald M. Atwater, M.D., were appointed as members of this special committee with authority to include additional members as deemed desirable. In consultation with Friend Lee Mickle, Sc.D., Edmund K. Kline, Dr.P.H., and Francis B. Elder, the following proposal for an Association-wide Coördinating Committee on Laboratory Methods has been developed.

It has been accepted in principle by the Engineering and Laboratory Section Councils and the Laboratory Section Coördinating Committee. Comments from the Membership of the Association will be welcomed and considered by the special committee in preparing its report and recommendation to the Committee on Research and Standards at the Annual Meeting in Atlantic City.

OUTLINE OF A SUGGESTED ORGANIZATION FOR AN ASSOCIATION COÖRDINATING COMMITTEE FOR LABORATORY METHODS

1. Basic components of the Committee:

1.1 *The Coördinating Committee* to be a subcommittee of the Committee on Research and Standards. Members, from the appropriate Sections and/or from among the chairmen of Laboratory Methods Committees, will be appointed by the Committee on Research and Standards on the basis of their individual qualifications to perform the job assigned to the Coördinating Committee. The chairman of the committee will be regarded a member *ex officio* of the Committee on Research and Standards, if not already on that committee.

1.2 *The Chairmen of Laboratory Methods Committees* will be appointed by the Coördinating Committee; other members will be appointed by the chairman of the Coördinating Committee. All such appointments will be made in consultation with the Section Councils involved. The appointment of members of any Laboratory Methods Committee will be subject to approval by the Section Council of the Section to which the appointees belong. There shall be only one Laboratory Methods

Committee active in the preparation of "Methods" in any particular field. Appointment to "Methods" committees of persons not members of the American Public Health Association is permissible.

1.3 *The Coördinating Committee* shall appoint the A.P.H.A. representatives to any Joint Editorial Board concerned with interests of other organizations after approval of its nominations by the Executive Board. The Coördinating Committee shall also appoint any special editorial committees necessary for preparing A.P.H.A. Standard Methods Committees.

2. Duties and Functions:

2.1 *The Coördinating Committee* will:

2.11 Assume leadership among existing Laboratory Methods Committees.

2.12 Establish Laboratory Methods Committees upon the recommendation of any Section or as deemed necessary.

2.13 In consultation with Section Councils involved, appoint a chairman of each Laboratory Methods Com-

mittee. Committee members will be appointed by the chairman of the Coördinating Committee after consultation with the chairman of the committee concerned.

- 2.14 Assure competent, adequate group review of any Laboratory Methods by its committee. This may extend to the preparation of guiding rules of procedure for any Laboratory Methods Committee.
- 2.15 Promote the preparation of new Laboratory Methods and timely review of existing reports.
- 2.16 Resolve controversial questions that may not be possible of solution in the committee involved.
- 2.17 Establish uniform style, format, etc., to be followed in the preparation of any Laboratory Method other than those under direction of a Joint Editorial Board.
- 2.18 Present to the Committee on Research and Standards completed manuscripts with the assurance that competent group judgment has been obtained in their preparation.
- 2.2 *Laboratory Methods Committees* will:
 - 2.21 Arrange for allocation of material to proper persons for preparation.
 - 2.22 Arrange for review of entire manuscript by the full committee.
 - 2.23 Refer irreconcilable questions to the Coördinating Committee.
 - 2.24 Prepare not only methods to be adopted as, "Standard Methods," but any others to be published.
 - 2.25 Assure coördination of views of those interested in the development of laboratory methods with those interested in the interpretation and application of those methods, and vice versa.
- 2.3 *Association Sections or Their Councils* will:
 - 2.31 Recommend to the Coördinating Committee the formation of new Laboratory Methods Committees as the need arises.
 - 2.32 Confirm appointments to a Laboratory Methods Committee of members affiliated with the Section.
 - 2.33 Request the Coördinating Committee for representation on any Laboratory Methods Committee

in which the Section is interested either from the laboratory or field implications.

2.4 *Joint Editorial Board Representative(s)* will:

- 2.41 Represent the Association in the preparation of uniform procedures and allocation of areas of responsibility to the organizations sponsoring the publications.
- 2.42 Refer back to the Coördinating Committee any subjects which cannot be settled by Joint Editorial Board action.
- 2.43 Be limited to editing duties. They will not have any judicial responsibilities.

It is believed that the chief weaknesses in the present Coördinating Committee functioning are eliminated under the proposed Committee on Research and Standards Coördinating Committee. It would assure representation of all Sections indicating their basic interest in the activities of a laboratory methods committee. Possible duplication of committees would be prevented. Representation of both the worker in strictly laboratory procedures and the field man would be assured by proper committee appointments. Formal Association adoption of a method would be simplified in that any text would clear the laboratory method committee preparing it, then go to the Committee on Research and Standards. Following approval by that committee, only Governing Council action would be required for adoption as an official Association volume.

WHAT HAVE YOU FOR HEALTH EDUCATION HEADQUARTERS AT ATLANTIC CITY?

All health agencies are invited to send their health education and publicity materials to the National Publicity Council for possible inclusion in the portfolios now being prepared for display at the 75th Annual Meeting. The materials will be exhibited in the Health Education and Publicity Headquarters

- mittee. Committee members will be appointed by the chairman of the Coördinating Committee after consultation with the chairman of the committee concerned.
- 2.14 Assure competent, adequate group review of any Laboratory Methods by its committee. This may extend to the preparation of guiding rules of procedure for any Laboratory Methods Committee.
 - 2.15 Promote the preparation of new Laboratory Methods and timely review of existing reports.
 - 2.16 Resolve controversial questions that may not be possible of solution in the committee involved.
 - 2.17 Establish uniform style, format, etc., to be followed in the preparation of any Laboratory Method other than those under direction of a Joint Editorial Board.
 - 2.18 Present to the Committee on Research and Standards completed manuscripts with the assurance that competent group judgment has been obtained in their preparation.
- 2.2 *Laboratory Methods Committees* will:
- 2.21 Arrange for allocation of material to proper persons for preparation.
 - 2.22 Arrange for review of entire manuscript by the full committee.
 - 2.23 Refer irreconcilable questions to the Coördinating Committee.
 - 2.24 Prepare not only methods to be adopted as, "Standard Methods," but any others to be published.
 - 2.25 Assure coördination of views of those interested in the development of laboratory methods with those interested in the interpretation and application of those methods, and vice versa.
- 2.3 *Association Sections or Their Councils* will:
- 2.31 Recommend to the Coördinating Committee the formation of new Laboratory Methods Committees as the need arises.
 - 2.32 Confirm appointments to a Laboratory Methods Committee of members affiliated with the Section.
 - 2.33 Request the Coördinating Committee for representation on any Laboratory Methods Committee
- in which the Section is interested either from the laboratory or field implications.
- 2.4 *Joint Editorial Board Representative(s)* will:
- 2.41 Represent the Association in the preparation of uniform procedures and allocation of areas of responsibility to the organizations sponsoring the publications.
 - 2.42 Refer back to the Coördinating Committee any subjects which cannot be settled by Joint Editorial Board action.
 - 2.43 Be limited to editing duties. They will not have any judicial responsibilities.
- It is believed that the chief weaknesses in the present Coördinating Committee functioning are eliminated under the proposed Committee on Research and Standards Coördinating Committee. It would assure representation of all Sections indicating their basic interest in the activities of a laboratory methods committee. Possible duplication of committees would be prevented. Representation of both the worker in strictly laboratory procedures and the field man would be assured by proper committee appointments. Formal Association adoption of a method would be simplified in that any text would clear the laboratory method committee preparing it, then go to the Committee on Research and Standards. Following approval by that committee, only Governing Council action would be required for adoption as an official Association volume.

WHAT HAVE YOU FOR HEALTH EDUCATION HEADQUARTERS AT ATLANTIC CITY?

All health agencies are invited to send their health education and publicity materials to the National Publicity Council for possible inclusion in the portfolios now being prepared for display at the 75th Annual Meeting. The materials will be exhibited in the Health Education and Publicity Headquarters

Opportunities Wanted

Public health physician is available for administrative appointment; Ph.B. degree and Doctor of Medicine degree, Eastern university; M.S. degree in Public Health Medicine; seven years' public health work which has been largely administrative; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Health educator; B.S., M.S. and Ph.D. degrees; several years, instructor in biology, bacteriology and health; state university; three years, public health educator, city and county health department; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Public health nurse is available for administrative position in public health, Bachelor of Science in Education with major in Public Health nursing; past several years, supervisor public health staff, important war project; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Sanitary engineer is available for public health appointment; C.E., Eastern university; two years' municipal engineering including supervision of field personnel; six years, sanitary engineer with state department of health where he has obtained broad experience in all phases of environmental sanitation; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

NEWS FROM THE FIELD

WORLD HEALTH ORGANIZATION

July 22 will mark the first full year since the establishment of the World Health Organization. On July 22, 1946, 61 nations met in New York to sign the Constitution and establish the World Health Organization as a specialized agency of the United Nations.

An Interim Commission was established to carry on the health duties pending the ratification of the Constitution by 26 members of the United Nations. In the past year ratifications have not been as rapid as many had expected. By June 1 only nine members of UN (and three non-members) had ratified the document. Unfortunately these did not include the United States. Although Secretary of State George C. Marshall had placed the ratification of the WHO Constitution high on his priority list for foreign affairs this spring, by June 1 the matter had not come before either the Senate or the House for formal action. It is reported that no objection to approval of the Constitution exists, but that pressure of emergency foreign affairs has prevented the proposition from reaching the calendar.

In the past year considerable progress has been made in the international health field through continuing health programs and new projects instituted by WHO. The health programs of the League of Nations, UNRRA, and the Office International d'Hygiène Publique were taken over. This involved continuing the world-wide work in epidemiological reporting with issuance in French and English of *The Weekly Epidemiological Record* and transmission of notifications by letter, cable, and radio. The Singapore Epidemiological Station was taken over on April 1 with

facilities for broadcasting data to the Far East via several radio stations.

Biological standardization work has been continued, and on June 9 a meeting of the Expert Committee on Biological Standardization was held in Geneva.

The Interim Commission is now sponsoring health programs in Greece, Ethiopia, and China, as well as an international fellowship program, all previously carried by UNRRA. DDT spraying from airplanes and house spraying are proving effective in bringing malaria under control in Greece. WHO experts are coöperating with Greek health officials in efforts to reduce the incidence of tuberculosis.

Some 34 technical health people are working in coöperation with official Chinese agencies to train medical, dental, health, and nursing personnel.

An expert team is being sent into Yugoslavia to train personnel in plastic surgery.

More than 200 fellowships are being granted in 1947. Only countries which received UNRRA aid are eligible to appoint fellows. Ten per cent of the fellowships have been allocated to work in pediatrics and child health.

The WHO during its first year instituted a promising program of expert committees. Three committees had already met by June 1. The Expert Committee for the Preparation of the Sixth Decennial Revision of the *International Lists of Diseases and Causes of Death* met in Ottawa March 10-19 and prepared an extensive report of recommendations. The Expert Sub-Committee for the Revision of the Pilgrimage Clauses of the International Sanitary Conventions made a field study in the Red Sea area April 16-24, and the Ex-

pert Committee on Malaria met in Geneva April 21-26.

Other expert groups appointed include those on quarantine, yellow fever, habit-forming drugs, revision of conventions, and tuberculosis.

Of particular interest to public health workers is the program of technical publications approved at the third session of the Interim Commission in April, 1947. A monthly *Chronicle of the World Health Organization Interim Commission* will be published in English, French, Spanish, Chinese, and Russian. For 1947 two issues of the *Bulletin of the World Health Organization—Interim Commission* and two issues of the *Digest of Health Legislation* were approved.

PROPOSED FEDERAL PROGRAM ON CIRCULATORY DISEASES

On February 26 Senator Claude Pepper of Florida introduced a Bill (S.720) which has been referred to the Committee on Labor and Public Welfare, authorizing and requesting the President to undertake to mobilize at some convenient place or places in the United States an adequate number of the world's outstanding experts and to coördinate and utilize their services "in a supreme endeavor to discover new means of treating, curing, and preventing diseases of the heart and arteries."

The Bill briefly authorizes the President to undertake "in whatever manner he may deem most appropriate" to bring together outstanding experts from any country and to coördinate their services "through the Surgeon General of the United States," or through an independent group appointed by him." The President is also authorized to build needed clinical laboratory research facilities in order adequately to approach this problem, which, according to the Bill, involves the death of more than 587,000 persons a year in the United States and which causes dis-

ability to more than 7 million persons.

The Bill authorizes the sum of \$100,000,000 to be appropriated for these purposes.

DR. GODFREY RETIRES AS NEW YORK STATE COMMISSIONER OF HEALTH

On May 1, 1947, Edward S. Godfrey, M.D., retired as New York State Commissioner of Health after having served 30 years in the department, 11 of them as State Commissioner. He first joined the staff of the New York State Health Department in 1917 as epidemiologist. In 1936, he was appointed State Commissioner by Governor Lehman to succeed Thomas Parran, M.D., and was twice reappointed by Governor Dewey in 1944 and 1947.

After his graduation from the Virginia Medical School in 1903, Dr. Godfrey was in Arizona for 13 years, 4 of them as superintendent of public health of the Territory of Arizona and the remainder in private practice. In 1916 he became epidemiologist on the staff of the Illinois State Board of Health, and a year later was appointed epidemiologist of the New York State Department of Health. His service to New York State has been continuous since that date except for a period during World War I.

In 1920, Dr. Godfrey was appointed Director of the Division of Communicable Diseases of the State Health Department and later assistant Commissioner in charge of local health administration. During this period he developed practical methods of reducing mortality from measles and diphtheria, instituted a systematic control of typhoid carriers, reorganized the work of the 16 state health districts, and had general oversight of the work of some 800 local health officers. He has been recognized particularly for his work in communicable diseases and for his improvement of district public health services.

In 40 years of public health work, Dr. Godfrey has been associated in many important developments. He has contributed scientific articles to the literature on public health, notably reports on studies of measles in children's institutions and on the epidemiology of measles and of diphtheria. He is the author of the chapter on Epidemiology in Park's *Hygiene and Public Health*.

Dr. Godfrey is a founder and past-president of the American Epidemiological Society, a Fellow of the New York Academy of Medicine, the American Medical Association, and the American Public Health Association. He was President of this Association in 1939-1940 and has been active in its affairs for many years. Currently he is Chairman of the Committee on Constitution and By-Laws and is a member of the Committee on Professional Education.

DR. SABIN FIRST WINNER OF JANE ADDAMS MEDAL

Rockford College (Ill.) recently celebrated its 100th anniversary. As a part of the centenary services, it awarded the Jane Addams Medal for distinguished service by an American woman to Florence Rena Sabin, M.D., of Denver in recognition of her "untiring achievements" in public health work in Colorado. Dr. Sabin is the first winner of this newly established award.

SOUTHERN BRANCH ANNUAL MEETING

The Southern Branch of the American Public Health Association met in Memphis, April 21-23, with 3 general and 8 section meetings. Carl Buck, Dr.P.H., Field Director of the Association addressed the Health Officers Section on The Next Important Steps in Public Health; William T. Ingram, Engineering Field Associate, participated in the program of the Sanitation Officers Section on discussing the Technique of Evaluation of a Sanitation Program of a Local Health Unit; and

Charles B. Frasher, Merit System Field Associate, spoke before a joint session of five sections on Merit Systems.

Officers for the coming year were elected as follows:

President—John W. Williams, Jr., M.D.
First Vice-President—G. S. T. Peeples, M.D.
Second Vice-President—O. C. Hopkins
Secretary-Treasurer—John W. Whitney, M.D.
Representative on Governing Council—Robert H. Riley, M.D.

All except the last mentioned have served during the past year and were reelected for a term of another year.

ALMROTH WRIGHT, TYPHOID HERO, DIES

Sir Almroth Edward Wright, the introducer of antityphoid inoculation, died in London on April 30. He was 85 years old.

The famous bacteriologist had been credited with saving more than 100,000 lives of British soldiers in World War I through his use of typhoid inoculations. He also did much valuable work in the preparation of other vaccines, such as those for tuberculosis and pneumonia.

Sir Almroth was head of the Institute of Pathology at St. Mary's Hospital in London from 1902 until his retirement in June, 1946. His assistant and colleague for many years was Sir Alexander Fleming, the discoverer of penicillin.

COMMONWEALTH FUND APPOINTS NEW DIRECTOR

Donal Sheehan, M.D., has been appointed General Director of the Commonwealth Fund. He will take office on September 1, the effective date of the retirement of the present director, Barry C. Smith. Dr. Sheehan is professor of anatomy of the New York University College of Medicine.

Dr. Sheehan, born in England forty years ago, was educated at the University of Manchester. After postgraduate study at Vienna, Breslau, and Amsterdam, and at McGill and Yale, and two

years' teaching of neuro-anatomy at Manchester, he joined the medical faculty of New York University in 1937. As acting dean of the College of Medicine during the war he was a leader in planning the reconstruction of its medical curriculum and in preparing a program for its development which, according to Dr. Harry Woodburn Chase, chancellor of the university, contains "what is most vital in present-day medical thinking."

Dr. Sheehan is a trustee of the Josiah Macy, Jr., Foundation and recently completed a mission in Czechoslovakia for the Rockefeller Foundation.

NEW MEXICO PUBLIC HEALTH ASSOCIATION

At its Annual Business Meeting held on May 21 in Albuquerque, the New Mexico Public Health Association elected the following new officers:

President: C. E. Kaufman, M.D., Silver City
President-elect: Mrs. Eunice L. Vandervoort, Santa Fe
Vice-President: Mrs. Gerald Hein, Clovis

Dr. James R. Scott is the representative of the New Mexico society on the A.P.H.A. Governing Council. The Secretary-Treasurer is Leon du Flon of Albuquerque.

STATE DIRECTORS OF LOCAL HEALTH SERVICES MEET

The first annual meeting of the newly organized Association of State and Territorial Directors of Local Health Services met in Topeka, Kans., on April 10 and 11. It adopted a Constitution and By-Laws, elected officers, and discussed the problems of local health service—state legislation, 1948 fiscal budgets, local-state relationships, and personnel recruitment and training.

The following officers were elected for the ensuing year:

President: Monroe F. Brown, M.D., Director of Local Health Service, Tennessee State Health Department

1st Vice-President: John W. Shackelford, M.D., Director of Local Health Service, Oklahoma State Health Department

2nd Vice-President: V. A. Van Volkenburgh, M.D., Assistant Commissioner of Health, New York State Health Department

Secretary: Richard F. Boyd, M.D., Chief, Division of Local Health Administration, Illinois Department of Public Health

Members of Executive Council:

George Dame, M.D., Director, Bureau of Local Health Service, Florida State Health Department

J. K. Altland, M.D., Director, Bureau of Local Health Service, Michigan State Health Department

DR. FERREE TO NATIONAL HEALTH COUNCIL

John W. Ferree, M.D., on May 1 began his duties as an associate director of the National Health Council. He is engaged principally in helping local, county, and state health councils to broaden the scope of their usefulness, and in stimulating the formation of local health councils wherever they would advance the effectiveness of community and state health agencies.

Dr. Ferree was Indiana State Health Officer between 1940 and 1942, and director of its Bureau of Local Health Administration for four years previously. During the war he served in the U. S. Navy as officer in charge of the Venereal Disease Control Section of the Division of Preventive Medicine, returning in 1945 with the rank of Commander. Since that time he has served on the staff of the American Social Hygiene Association.

HEALTH COUNCIL OF GREATER NEW YORK COMPLETES ITS FIRST YEAR

On April 30 the first year's report of the Health Council of Greater New York was made at a meeting in New York. Among its items is a brief history which indicates that the Council was established through the financial aid of the American Red Cross and after a six month survey of the need for such a council. Pledges from this agency

and foundations will make available approximately \$50,000 a year for five years.

Bailey B. Burritt, Co-Chairman of the Long-Range Planning Committee recommended a plan for a broad survey of the city's health needs and facilities and the subsequent development of a master health plan for the city. This will entail weekly hearings, "town meetings for health," when experts will present the needs and when the Council's area of activity and its relationship with other coordinating agencies will be defined.

HUMAN RELATIONS QUARTERLY

Human Relations, a new quarterly journal has been organized to serve as a channel in which work in the various social sciences may converge for comparative study at an international level. Need for it arises from a growing necessity to integrate the social sciences. It will supplement the more specialized journals by providing side by side comparison of related work in sociology, psychology, economics, anthropology, psychiatry, and other disciplines. It is a project jointly of the Tavistock Institute of Human Relations, London, and the Research Center for Group Dynamics, Massachusetts Institute of Technology, Cambridge, Mass.

The first issue will appear shortly. The annual subscription is \$7.00. Editorial correspondence and contributions should be addressed to Dorwin Cartwright, Chairman, American Editorial Committee.

WHO SPONSORS "FACULTY ON WHEELS" TO AUSTRIA AND HUNGARY

The first travelling teaching unit sponsored by the World Health Organization Interim Commission is touring Austria and Hungary during July and August to show advances in medical research and practices on a truly interna-

tional scale. Its members will travel as a group to the various medical centers, lecturing, participating in conferences, and demonstrating new surgical techniques and the use of some of the more recently developed sera and drugs.

In reporting this program, Dr. Brock Chisholm, Executive Secretary of the Interim Commission, said, "Thousands of doctors all over the world have lived behind the curtain of censorship during the war years, working alone and unable to share in the knowledge of their associates in other countries. Only a few will be able to travel to centers of new research. This is why top-ranking specialists in a dozen fields are volunteering for this two month visitation to hospitals, clinics and universities in the two countries."

The American Unitarian Association, which had previously sent similar missions to Poland and Czechoslovakia in 1946 under the sponsorship of UNRRA, is undertaking this mission at the request of the Interim Commission. The ten man team, made up of eight Americans and two Swiss, will include specialists in physiology, pharmacology, cancer research, public health, surgery anesthesia, internal medicine and psychiatry.

The members of this mobile teaching unit are:

Maurice B. Visscher, M.D., Professor and Head of Department of Physiology, University of Minnesota, *Chairman*

Arwin Kohn, Director of Medical Projects, American Unitarian Association, Executive Director

John J. Bittner, Professor and Director of Cancer Research, University of Minnesota

McKeen Cattell, M.D., Professor and Head of Department of Pharmacology, Cornell University College of Medicine

Stuart C. Cullen, M.D., Professor and Chairman of the Division of Anesthesiology, University of Iowa

Joseph P. Evans, M.D., Associate Professor of Surgery, University of Cincinnati College of Medicine

Chester M. Jones, M.D., Clinical Professor of Medicine, Harvard Medical School

S. Bernard Wortis, M.D., Professor and Head

of the Department of Psychiatry, New York University College of Medicine

Eric Martin, M.D., Professor of Medicine and Director of the Medical Polyclinic, University of Geneva

Hermann Mooser, M.D., Professor of Bacteriology and Hygiene, and Director, Institute of Hygiene, University of Zurich

NATIONAL INSTITUTE OF SOCIAL
SCIENCES MEDAL TO
KATHARINE LENROOT

Katharine Lenroot, Chief of the U. S. Children's Bureau, was recently awarded the Gold Medal of the National Institute of Social Sciences for distinguished services to humanity. Presented to Miss Lenroot by G. Howland Shaw, former chief, division of foreign service personnel of the State Department, the citation reads as follows:

"As chief of the Children's Bureau, you have with true humanitarian spirit and sympathetic understanding devoted yourself to the welfare of children and child life in America. To the youth of today who will be the men and women of tomorrow, you have brought new hope to meet life's responsibilities and greater opportunity to lead happier and more useful lives."

FORMATION OF INTER-AMERICAN
ASSOCIATION OF SANITARY
ENGINEERING

Twice during 1946, representatives of sanitary engineering and sanitation from the various 21 American republics gathered together to discuss mutual problems and goals. The first meeting was held in Rio de Janeiro, Brazil, the second in Caracas, Venezuela. (See August and September issues, 1946, *A.J.P.H.*, News from the Field, for further details.) Out of these meetings came a firm belief that an understanding between the peoples living in the various American republics could be accomplished most effectively through social, professional, and economic coöperation. It was the unanimous opinion of the representatives attending the conference that formation of an Inter-American engineering group would do more than

foster better understanding between the peoples of the Americas. The group also agreed that such an organization could aid materially in improving public health and economic well-being by improving the application of the sanitary sciences.

Announcement is made by Homer J. Hayward, U. S. Representative on the Membership Committee, of formal plans for the formation of The Inter-American Association of Sanitary Engineering. The purpose of the Organization is:

The principal object of the Association is to reach by common agreement the solution of problems relating to sanitation and the establishment of standards for the uniform and continuous protection of the people of the hemisphere. This purpose may be accomplished by the following means:

- a. Deveopment of sanitary engineering.
- b. An interchange of ideas and scientific information concerning deveopments of Sanitary Engineering in the Americas.
- c. Establishment of standards of sanitation for the Americas.
- d. Promote more rapid advancement in the sanitation of the several countries of America as a necessary basis for economic and social development.
- e. Establish good will and better understanding among the persons engaged in sanitation work in the Americas.

Membership is open to engineers and others engaged in sanitation activities in official, nonofficial, or commercial organizations. Yearly dues are \$3 with a \$2 initiation. The initiation fee will be waived in the case of all applying for membership prior to the next conference in November, 1947. Membership prior to the November, 1947, meeting will entitle the individual to the classification of "Charter Member," also. The yearly dues will include subscription to the official publication which will appear on a quarterly basis.

Application blanks for membership can be obtained from Mr. Hayward, Inter-American Association of Sanitary Engineers, N.W. Corner, 17th and Constitution Ave., Washington 6, D. C.

PERSONALS

Central States

GEORGE D. BRIGHAM, PH.D.,* formerly Senior Bacteriologist, Pitman-Moore Biological Laboratory, Zionsville, Ind., has been appointed Assistant to the Director, Biological, Manufacturing and Finishing Division, Parke, Davis & Company, Detroit, Mich.

WILLIAM C. HARRISON, M.D.,† formerly of Minneapolis, became Director of the Delta-Menominee district health department at Powers, Mich., on July 1, after receiving the master's degree in public health from the Michigan School of Public Health.

RUSSELL E. PLEUNE, M.D.,† has resigned as Director. Northern Peninsula office, Michigan State Department of Health, and has accepted the position of Chief, Tuberculosis Section, McCloskey Veterans' Hospital, Temple, Tex.

R. E. SERFLING† is the head of the new Division of Public Health Statistics in Indiana. H. M. WRIGHT, remains as Director of Vital Records.

JOHN B. YOUMANS, M.D., Dean of the University of Illinois College of Medicine, Chicago, left April 11 for Berlin, Germany, to serve as nutrition consultant in a survey of the American, British, and French occupation zones by a twelve man committee.

Eastern States

CHARLES A. R. CONNOR, M.D.,† was recently appointed as Associate Medical Director of the American Heart Association, New York, N. Y., to work with DAVID D. RUTSTEIN, M.D.,* Medical Director, in the development of the Association's Program of research, service, and public education in diseases of the heart and circulation. Dr. Connor entered on active duty in the U. S. Army in 1942. He was active in the Air Sur-

geon's Rheumatic Fever Control Program and was the editor of its monthly newsletter.

CAMERON ST. CLAIR GUILD, M.D.,* was appointed as assistant chief of the tuberculosis section of the Veterans Administration Branch Office No. 2 at New York City, beginning May 1. He was formerly executive secretary of the American Trudeau Society and director of special programs for the National Tuberculosis Association, New York, N. Y.

W. ALLEN LONGSHORE, JR., M.D.,† began his duties recently as Deputy Commissioner of the Ulster County, N. Y., Health Department, following completion of work for the degree of Master of Public Health at Johns Hopkins University. During the war he served with a medical relief unit in India, China, and Mexico and since 1946 has been in the New York State Health Department.

NEW PERSONNEL IN THE MASSACHUSETTS STATE DEPARTMENT OF HEALTH:

ROBERT E. S. KELLEY, Captain MC, USN (Ret.), and ROBERT G. BENSON have been appointed to the Division of Biologic Laboratories, the former as physician in charge of the 2nd Mobile Unit and the latter as field supervisor of the Blood Donor Program.

WALTER J. PENNELL, Captain MC, USN (Ret.), and PAUL RICHMOND, Captain MC, USN (Ret.), have been appointed District Health Officers respectively of the Northeastern and the Worcester District.

VICTORIA M. CASS, M.D., CLAIRE F. RYDER, M.D., BROOKS RYDER, M.D., and JOSEPH H. HANSON, M.D., have been appointed as Epi-

* Fellow, A.P.H.A.
† Member, A.P.H.A.

demiologists, the first two in the Division of Administration, the third in the Division of Local Health Administration, and the last named in the Division of Communicable Disease.

ISAH L. SALZMAN and MARGARET M. HAEHNEL have been appointed as Social Workers in the Northeastern and South Metropolitan districts respectively.

NICHOLAS J. FIUMARA, M.D.,† formerly Health Officer of the Berkshire District, has been promoted to Director of the Division of Venereal Diseases, State Department of Public Health, pending qualification by the Division of Civil Service. He succeeds the late GEORGE E. PERKINS, M.D.

A. GARALDINE WHITE has been appointed Research Consultant in the Child Growth and Development Program, Division of Maternal and Child Health.

MARY CARR BAKER has been appointed Personnel Training Coordinator.

ALFRED NEWTON RICHARDS, Professor of Pharmacology at the University of Pennsylvania Medical School, and winner of one of the 1946 Lasker Awards of the A.P.H.A., on July 1 took office as President of the National Academy of Sciences for a four year term.

THOMAS M. RIVERS, M.D.,* Director of the Hospital of the Rockefeller Institute for Medical Research, New York, delivered the annual Cutter Lecture on preventive medicine at Harvard University School of Public Health, Boston, April 22, on public health aspects of infectious disease.

WILLIAM H. SAVIN has been appointed National Director of the American Epilepsy League, Inc., Boston. Just released from the army as lieutenant colonel, Mr. Savin spent 3 years in military government in Italy. He was

formerly executive director of the Family Service Association, Washington, D. C.

ELLEN THAYER, editor-in-chief for the Division of Publications and a member of the Commonwealth Fund staff since 1930, retired on March 31. BEULAH DIMMICK CHASE, since 1941 editor of publications at the Metropolitan Museum of Art, New York, N. Y., has succeeded her.

PAULINE BROOKS WILLIAMSON* recently retired as Chief of the School Health Bureau of the Metropolitan Life Insurance Company, New York, N. Y., a position she has held since the Bureau was first organized in 1925. She will continue as a member of Metropolitan's Advisory Educational Group and will serve as consultant to various groups. She was succeeded by MARJORIE L. CRAIG,* who has been in the School Health Bureau since 1937, for the last 3 years as Assistant Director.

Southern States

H. T. BAUGH, M.D., has accepted the directorship of the tri-county Becker, Custer, and Washita Health Department with headquarters at Clinton, Okla., according to an announcement made by JOHN W. SHACKELFORD, M.D.,* the state's Director of Local Health Services.

ELMER C. KEFAUVER, M.D.,† for 20 years Health Officer of Frederick County and also of the city of Frederick, Md., retired July 1. DONALD J. ROOP, M.D., who was recently appointed assistant health officer succeeded Dr. Kefauver.

W. L. MUSSER, M.D., a McGill graduate, on May 15 became Health Officer of Pike County, Mississippi, which has been without a health officer since November 1945.

ROY T. REM, Acting Director of the Division of Public Health Education of the Arkansas State Health De-

partment, has returned to Arkansas after securing the degree of Master of Public Health from the Yale University School of Public Health.

MARGARET RICE, M.Sc.,† was appointed supervisor of Public Health Statistics in the Mississippi State Department of Health on February 3.

ERNEST L. STEBBINS, M.D., M.P.H.,* Professor of Public Health Administration, Johns Hopkins University, Baltimore, Md., has been appointed Chairman of the Advisory Board on Health Services of the American Red Cross.

Western States

C. S. AMBROSE, M.D., has been appointed Health Officer of Tulare County, Calif., to succeed CHARLES C. HEDGES, M.D.

LAMAR A. BYERS, M.D., M.P.H.,† has joined the staff of the Washington State Department of Health as Supervisor of Crippled Children's Services. Dr. Byers has served as a health officer in both Tennessee and Texas.

JAMES T. GOOGE, M.D.,* has been named Clatsop County Health Officer by the Clatsop County Commissioners, Oregon. He has served as Director of Local Health Services in the Florida Health Department, was Assistant State Health Officer in Nebraska, and most recently was with the United Nations Relief and Rehabilitation Administration as Regional Medical Officer in China.

HARVEY F. HENDRICKSON, M.D., has been appointed to assist J. B. ASKEW, M.D., in the administration of the Bureau of Hospital Inspection, California's State Department of Health. During the past year, he has been assistant superintendent of the San Francisco City and County Hospital.

GLEN H. HOWE has joined the staff of

the Oregon State Board of Health as field inspector in the Bedding and Upholstering Section, Division of Sanitary Engineering.

RAYMOND E. LEACH,* recently discharged from military service with the rank of Lieutenant Colonel, Sanitary Corps, is now Director of Laboratories of the San Diego City and County Health Dept., Calif.

MABEL C. MCCONNELL was recently appointed to the staff of the Hawaii Territorial Department of Health as psychiatric social worker in the Division of Mental Hygiene. She will serve on the island of Kauai.

PHILIP MOORE, M.D., was recently appointed as Orthopedic Surgeon for Mt. Edgecumbe Hospital at Sitka, Alaska, and Orthopedic Consultant for the Territorial Department of Health. During the war he served as a lieutenant commander, U. S. Navy Medical Corps in various capacities. For the past 2 years Dr. Moore has been surgeon to the Greeley Clinic, Greeley, Colo.

CATHERINE SHERWOOD, M.D.,† arrived in Juneau in April to become Director of Maternal and Child Health and Crippled Children's Services, Alaska Department of Health, succeeding BERNETA BLOCK, M.D. Dr. Sherwood had previously been field pediatrician for the California State Department of Public Health and later Acting Health Officer of Ventura County, California.

PAUL SHIPLEY† took charge of statistics and records for the California Dept. of Public Health on June 1.

AUSTIN U. SIMPSON, M.D.,* head of the Washington State Health Department's laboratory section, was honored by his staff recently upon completing 26 years' service. He was presented with a congratulatory letter from the Governor and a gold watch. WILLIAM H. GAUB, Ph.D.,* has succeeded Dr. Simpson effective

Health Councils in Local Communities*

BLEECKER MARQUETTE, F.A.P.H.A.

Executive Secretary, Public Health Federation, Cincinnati, Ohio

THE health council is potentially one of the most valuable and powerful health forces in a community"—so the Gunn-Platt Study of Voluntary Health Agencies concluded.

WHEN TEAMWORK IS LACKING

A look at the situation in a Midwest city may serve to show what can happen when there is no machinery to coordinate the many and varied groups carrying on some phase of health work or to plan for the community's health.

This particular city has a population of about 400,000 and the county an additional 100,000.

The city and the county health departments are both very poor—woefully understaffed and inadequately financed. Nobody is doing anything to try to get more money for the departments, to raise their standards, or to study the possibility of combining the two into one centralized department so that every dollar available for official health department service may produce maximum benefit to the community.

The dental society, working alone and without help from any quarter, is doing all that is being done in dental

health, but this is limited to lectures and exhibits in the public schools. There is no program for prophylaxis and there are no clinics for treatment.

In nursing they have a bedside service rendered by insurance companies to their own policy holders but no such service for others, some nurses in the health departments but none in the schools. The shortage of nurses is serious in hospitals and in public health agencies. The professional nursing association is struggling with the problem, but there is no general community interest in it and no community program for meeting nursing needs.

The schools are just beginning to develop health education.

For the rapidly increasing numbers of chronic cases needing care, the county home provides custody only. Low-income patients go into the workhouse hospital when on rare occasions there happens to be a vacant bed. Nothing is being done to meet the broader problem.

There are no general medical clinics and no mental hygiene clinics.

The health department furnishes the staff for the tuberculosis clinic, but has to depend upon the tuberculosis association to furnish the building in which

* Special Review Article prepared at the request of the Editorial Board.

it operates, to pay the nurses and the cost of x-ray services.

An infantile paralysis committee collects funds but has no service program. The local branch of the American Cancer Society, besides fund raising, refers people to doctors. There is no educational campaign in regard to cancer.

Nothing is being done in a public health way about diabetes, heart disease, nutrition, or social hygiene.

Nobody has a comprehensive picture of the community's specific health needs. There is no organized way of bringing together interested citizens, the professions concerned, and health executives to study and plan for the community health.

WHEN HEALTH GROUPS PULL TOGETHER

Another Midwest city of not much larger size has had a health council for 30 years. The council is made up of representatives of every official health department, of every voluntary health agency, clinic, and hospital, of the medical, dental, nursing, and pharmacy associations, of civic and social agencies with a direct public health interest. It meets annually to receive reports on the work done and to elect officers and members-at-large to the coordinating committee. This committee is the governing body and meets monthly. The health commissioners are ex-officio members of the coordinating committee. The four professional societies, by constitutional provision, are each entitled to name a member of the coordinating committee. The health council has 13 divisions, each conducting its own program subject to coordinating committee approval. Each division elects its own chairman who serves on the coordinating committee. There are, in addition, a number of subcommittees, some regular and some temporary, dealing with special problems.

In this community the heads of all

health agencies are in touch with what other groups are doing, and they join in continuing study of health problems and programs. There is a minimum of friction and misunderstanding and an awareness of gaps in the community health program.

In all, there are some 500 people, delegates, and division members, participating in the work of the health council. Each month they receive reports on current health developments. As a problem arises calling for united action they are alerted.

The council recognizes the health departments as the proper center of public health activities and does everything in its power to strengthen these departments and help them to secure adequate budgets. They, in turn, have participated wholeheartedly in the coordinated effort to promote the public health. The council believes that the several health departments in the county should be centralized in a single department and has consistently, but so far unsuccessfully, worked to that end.

The council adheres to the policy that when an official department expresses its readiness to take over an activity of a voluntary agency, the transfer should be made without quibble. On the other hand, it scrupulously observes the autonomy of its affiliated agencies and avoids competing with them in any way.

Programs of the various health agencies are constantly observed and from time to time recommendations for modification of programs are made—always on the basis of careful study and with no attempt to force action on any recommendation. As examples, hospital social service provided by voluntary agencies to two public hospitals was taken over by the hospitals; medical direction of an independent clinic was assumed by the College of Medicine while another free-lance clinic was transferred to the direction of the

department of health; a child health agency is gradually integrating certain of its functions with the city health department.

The council has a paid staff consisting of one part-time and three full-time executives, secretarial service, and two extraordinarily competent volunteers, one full-time and the other half-time, who serve just as conscientiously as anyone on the payroll and add great strength to the organization.

Research plays a vital role. Special studies of problems of agencies and institutions are made as the need develops. The tabulation and analysis of mortality statistics is a continuous function. One phase of these studies deals with mortality from various diseases in the different census tracts and compares the experience of various economic and racial groups. It serves to indicate sections of the city in which concentrated effort may be needed on particular problems. Another phase of the mortality studies is concerned with refined and adjusted bases of comparison of this community with comparable cities. In this way, the council learns whether the city is keeping pace with other communities and sometimes where special emphasis needs to be placed. As an example, it was found several years ago that the city's death rate was high from appendicitis. An intensive education campaign, undertaken jointly by the council and the medical society, succeeded over a period of years in reducing the city's rate below the average. Enteritis and diarrheal diseases also were found to take a higher than average toll. The combined efforts of the health department and other health groups has not so far succeeded in effecting substantial reduction in mortality from these causes, but the battle against them goes on. More recently it has been discovered that, after adjustment for age, the rate of death from home accidents is high. A com-

mittee made up of representatives of interested agencies is now at work on this problem.

Comprehensive health education is an important part of the program. It includes two weekly radio programs, feature articles in the press and, in addition, a daily series in one newspaper, a weekly item in another, and a specially illustrated feature in suburban and labor papers. Street cars and busses carry illustrated car cards continuously. Monthly health bulletins are sent to factories, drug stores, and public buildings. A four page leaflet on nutrition is distributed each second month to several thousand low income families. A special leaflet goes each month to members of Negro health clubs. The council provides "Public Health Notes" for the medical society's monthly *Journal of Medicine*. Health chairmen of the Parent-Teacher Association clubs receive a one page message which they read to their members at their monthly meetings. Copy for most of this material is reviewed by representatives of the medical society and the department of health, and most of it carries the names of the three organizations. Lectures, exhibits, and printed leaflets round out the education media used.

As examples of filling in gaps in the program, the establishment of a health center for Negroes where Negro doctors and dentists had their first opportunity locally for clinical experience, and the launching of what has grown to be a most successful central mental hygiene clinic may be mentioned.

The council directed successful campaigns for bond issues to provide better facilities for the city hospital and to build a new county home and chronic disease hospital. Several years ago it joined hands with the tuberculosis association in securing a bond issue which financed the modernization of the tuberculosis hospital.

The legislative committee keeps in

touch with local, state, and national legislation affecting health, and with the backing of its constituent agencies supports desirable bills and opposes objectionable measures.

The need of facilities for the care of the chronic sick and the shortage of nurses are among the problems facing this (and practically every) community. Both are receiving intensive study by local groups with a plan of action as the goal.

Support was given to a vigorous public campaign that led to the enactment of a strong ordinance for smoke control.

As an illustration of good inter-agency teamwork, the tuberculosis association is financing a vigorous joint program in nutrition, directed for the council's nutrition division by a well trained, full-time nutritionist.

Mortality studies having demonstrated excessive rates from certain preventable diseases in slum areas, the council is supporting the uphill battle for decent housing and is calling public attention to low income as an obstacle to health improvement.

A future objective is the development of a master plan for health.

ORGANIZATION OF HEALTH COUNCILS

The Gunn-Platt Report studied health committees, divisions, and councils set up in some 34 cities for the purpose of coordinating health activities. It states the purpose of a health council well in these words "to co-ordinate as far as possible the health thinking and planning of all the organizations, public and private, concerned with public health, including the medical, dental, and nursing professions. It studies the health needs of the community and endeavors to develop a community health program to meet those needs. It attempts to stimulate public interest in public health problems, and it may render common health

services in such fields as statistics, research, and health education. It usually expresses itself in matters of health legislation."

The National Committee of Health Council Executives has set down certain principles which it considers essential for the successful organization and functioning of a health council. Among them are: that it be representative of the recognized health forces of the community; that it be without limitation as to race or creed; that it have liaison with recreational and welfare organizations. Recognizing that the form of organization and operation will vary, depending upon local conditions, the health council in large communities, the National Committee states, needs a full-time staff and budget. The executive should have the necessary qualifications and should be chosen by the council in coöperation with the other local agencies involved. The council should determine its own policies but should work in the closest harmony with both the Council of Social Agencies and the Community Chest, where they exist.

From the results of a recent questionnaire survey of 31 cities known to have some kind of coördinating health agency, it is possible to draw some general conclusions as to how they are organized and what they attempt to do. Most of the councils are in cities of over 250,000 population and apparently very few in places of less than 100,000. They are organized almost uniformly under the sponsorship of a Community Chest or Council of Social Agencies—whether they be called health council, section, division, league, federation, or committee. With few exceptions, lay people and the public and private health agencies and the professional societies are represented. Usually, their scope is the county or metropolitan area. Invariably, they aim to promote co-ordination and joint community planning. In the larger communities there

is usually a paid executive but only rarely is the executive selected by the council itself. Few have their own budgets. Usually the Community Chest or the Council of Social Agencies selects the executive and meets the council's expenses out of its own budget. Almost without exception the council determines its own policy and program.

None of the 5 cities of less than 100,000 population has a paid executive.

Types of activity vary greatly. There is no general pattern. Nursing, convalescent care, dental hygiene, the chronic sick, special types of health education, mental health, nutrition, hospital care, surveys of community health facilities, and support of official health departments are among the problems most commonly receiving the attention of these councils.

Exact information as to how many health councils there are in the United States at the present time is not available.

SUCCESS OF HEALTH COUNCILS

The Gunn-Platt Report gives the results of its study of 32 health councils. Three-fourths of the 32 were found to be weak and ineffective. Four were rated excellent, and 4 good. Some of the reasons the Report gives for the poor rating of most of the councils are: an executive who lacks drive or has too many duties, inadequate funds, poor working relationship between the health council and the official health department.

There is no magic in the organization of a health council. If there is no such agency, there can be little chance of any real teamwork among health forces or of intelligent community planning. Where such an agency does exist, there is at least an opportunity for effective coordination of effort. But this will not come about automatically just because machinery is set up or a gesture made. A health council in any large community

needs a competent staff—at least an executive who has had enough training in health work to know what it is all about, and enough common sense to know that people have to be dealt with tactfully if they are to pool their efforts with those of others, and to be constantly conscious of the fact that a coordinating agency must give credit graciously and willingly to others and not seek all the credit for itself. The executive must have qualities of leadership and the ability to keep his groups interested, else they will gradually disintegrate. He must encourage them to participate in decisions so that they will feel that they are not looked upon as “rubber stamps.” He must have enough funds to do something about the major programs his groups decide upon. Otherwise they lose interest as they find that things do not get done and tire of fruitless meetings. He must recognize that the official health department is the hub of the wheel of public health, and not try to compete with or detract from the prestige of the health officer. If the health officer is incompetent, then there is a different problem—namely, to try to find ways and means of effecting a change.

The fact that some health councils are getting results shows that in a favorable situation the plan works. The fact that so many are weak indicates difficulties that must be overcome. One of these difficulties is certainly lack of trained people for the executive positions involved. This lack is not likely to be met until schools of public health train more people for public health work in general and give them some instruction in community organization and planning. Another is starvation budgets insufficient to pay adequate salaries and to implement an active program. In the larger communities, one executive staff member is not enough. He quickly becomes overwhelmed with a multiplicity of duties, with the result

that the council's programs remain on paper. Two ways in which financing of health councils might be met suggest themselves. One is that Community Chests recognize that community health problems will not be handled effectively, nor the individual health agencies in the Chest fulfil their best purpose, until there is dynamic health-coördinating machinery and that theirs is the responsibility for financing it. Another is that in sections of the country where the tuberculosis mortality has declined to the point that the problem is well in hand, local tuberculosis associations consider spending some of their funds to set up health councils where they do not exist or to help put them on a sound financial basis where they are starved for funds.

The rapid increase in fund-raising drives for health purposes and the establishment of new local agencies—infantile paralysis, cancer, heart, social hygiene, arthritis, alcoholism, cerebral palsy, multiple sclerosis, epilepsy—is complicating the already confused situation in local communities. Unless there is some kind of effort at co-ordinating the numerous activities going on in our communities, the public is likely to become more and more confused and health work more disparate and stratified.

HEALTH COÖRDINATION IN SMALL COMMUNITIES

How about small communities and counties? Do they have problems that require united planning and action? Does a health council or committee have anything to offer them? Unfortunately there is not much experience to go on, but what happened in Lewis County in the State of Washington is illuminating. This county of 42,000 population has no regulations governing the production and sale of milk. Being surrounded by counties that do have such regulations, it has been from time

to time the dumping ground for dairy products that could not be sold elsewhere. The same is true of meat inspection. There is no regulation of eating places. The community needs more hospital facilities and more doctors and dentists.

According to an official of the State Health Department, these conditions exist "not because nobody cares about health problems, but because while many groups wanted something done, there just was not any machinery for getting people together to see that it was done." Some of the leaders began to wonder why they could not have some kind of an organization to present a united front when action was needed—to get an ordinance, to appear before the county commissioners, or to pull together in a joint campaign. Late in 1946, three citizens—one from the Tuberculosis League, one from the County Extension Service, and one from the Health Department—decided that what was needed was a health council. And now they have it, with representatives of these three groups and, in addition, a considerable number of organizations, including the schools, the Grange, the County Medical Society, the Welfare Department, the Red Cross, the Junior Chamber of Commerce, the Medical Auxiliary, the Parent-Teacher Association, the Women's Council, the Cancer Control group, Kiwanis, Optimist Club, as well as dentists, nurses, county commissioners, legislators, and a considerable number of interested lay persons. The council has adopted a constitution, has a voluntary secretary, and meets alternately in the two largest towns in the county.

The first problem that came before the new-born council was where to locate a new hospital for which a bond issue had just been voted. The citizens of each of the two largest cities quite naturally want the hospital in their town.

The only thing agreed upon is that more hospital beds are needed and needed quickly. And so the Health Council has stepped in and is grappling with the problem of finding some acceptable solution.

Says the state health official, "the Health Council will see to it that the need for more beds doesn't 'die in committee' because its job is to keep health needs before the people. In similar ways it will go on to other problems, like obtaining good ordinances governing food handling and milk supplies, getting more doctors and dentists to serve its people, doing something about the shortage of nurses, getting a playground and a swimming pool, and so on down the long line of health needs. The Health Council will bring to these projects the support of organized groups and of citizens and cooperatively solutions will be worked out."

Not every county has needs exactly the same as those of this western community, but it would not be easy to find one that has none. Almost invariably there are a number of groups engaging in or interested in some kind of health work—the professional medical, dental, and nursing societies, the health department, the Red Cross, a tuberculosis association, an infantile paralysis committee, a branch of the American Cancer Society, the schools, a Parent-Teacher Association. It just seems common sense that if these groups can be brought together to pool their knowledge, study their problems, and plan for action, they can get things done that just will not come about so long as there is no "united front."

The plan for organization of a health council for a small county will be of the simplest. What is needed is some kind of agency, whatever it may be called, in which representatives of the interested groups can be brought together regularly to study their prob-

lems, decide what their needs are, and join hands for a common program. Certainly no such community will be able to afford or, in fact, need a full-time paid executive. An interested member of the staff of some one of the health groups may well serve as secretary.

It is unlikely that county health councils will develop rapidly, because most citizens of small counties are not likely to be keenly aware of their health problems, and because leaders with the vision and the drive essential to get a council organized and keep it going are rare. Those facts do not argue that the health council plan is not adapted to such communities or that it will not work under favorable conditions. At present few councils exist in counties that have no large cities or, if they do, information about them is lacking.

CONCLUSION

Sixteen years ago Howard Whipple Green, successful executive of the Cleveland Health Council, wrote "After more than 10 years' trial, it now seems clear that the fundamental procedure adopted by health councils is productive of favorable results. When provided with competent personnel, necessary funds, and able guidance, health councils have demonstrated an ability to exert leadership in the public health activities of their respective communities. They have been influential in obtaining the coördination of activities which previously were overlapping or disjointed, they have successfully sponsored the development of new health activities when needed; and, most important of all, they have carried on studies of health needs and have planned and, in considerable degree, brought to fruition programs of development based upon needs rather than upon impulse and guesswork."

Since that time, many new health

councils have been formed. The proportion of effective councils remains disappointingly small. The principal reasons for poor performance are lack of funds, of competent staff and of dynamic leadership. The plan is sound and it works when these requirements are met. Not until national and local leaders in the health field develop an awareness of the fact that "The health council is potentially one of the most valuable and powerful health forces in a community" will the three-fourths of the health councils that are weak be furnished with the ingredients that will make them strong or the many sizeable communities that lack machinery for united action on the health front fill in the present void. It would, indeed,

be unreasonable to expect health councils, even under ideal conditions, to perform miracles. No community with the best directed health council conceivable will solve all its problems. There will still be gaps and plenty of unmet needs. But the gaps and the unmet needs will almost certainly be highlighted with much greater chance that in due time something will be done about them than in the community that continues in ignorance of its own problems.

In the smaller communities, coordinating health machinery will develop slowly. Its pace will be quickened by more demonstrations that it is a practical and, under intelligent leadership, a useful tool for improving the community's health resources.

AMERICAN PUBLIC HEALTH ASSOCIATION

Need for Systematic Evaluation of Substandard Housing*

M. ALLEN POND, F.A.P.H.A.

*Assistant Professor of Public Health, Yale University School of Medicine,
New Haven, Conn.*

PUBLIC health workers have begun to realize that they cannot afford to take an ostrich-like attitude about housing. With the dawn of this new point of view, numerous questions have arisen involving the mechanics of carrying on a program in healthful housing. It is the purpose here to outline specific activities that may provide benchmarks for administrators who seriously intend to tackle their housing problems.

The history of the public health movement itself provides precedent for organizing a realistic program of housing sanitation. Modern public health had its origins about a century ago in surveys of health and laboring conditions carried on in England by Edwin Chadwick and Southwood Smith, and in this country by Lemuel Shattuck and Stephen Smith. Indeed, the superb work of Stephen Smith and his associates in studying New York slums 80 years ago led to the first housing sanitation program in the United States.¹ Just as these pioneering ventures focused attention on specific problems of moment to everyone, so might we expect intensive work in the hygiene of housing to be a product of an earnest and well directed study of modern health and housing conditions.

No wise public administrator would consider undertaking a program of action without having some basis of demonstrated need. Abraham Lincoln has stated this well: "If we could first know where we are and whither we are going, we could better judge what to do and how to do it." In the field of housing, health administrators have found that they need facts upon which to build a program. As a result of the Housing Census of 1940 and of many real property inventories, we know that approximately one-third of the population lives in substandard housing. In September, 1946, the National Housing Administrator reported that 2,000,000 married veterans were living doubled-up or in stop-gap quarters, and that 4,000,000 wanted to rent, buy, or build. It is the task of local officials to find those of their neighbors who are inadequately housed, and on the basis of those findings, to plan action which ultimately will lead to an improvement of housing through the elimination of slums and the arrest of spreading blight. Experience has shown that health authorities are well able to make these preliminary determinations.

Health departments have long been depositories of data on occupied housing, particularly multi-family units. However, a decade ago, when the public housing program began in the United States, health officers were not in position to use their files for detailed infor-

* Presented at a Joint Session of the Health Officers and Engineering Sections of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 14, 1946

mation on local housing conditions. Furthermore, few health officials today are in position to provide precise information on housing standards. Studies at the National Bureau of Standards of many state and local building codes and regulations have revealed phenomenal differences between basic requirements. For instance, local standards for light, heat, and ventilation are widely at variance, and evidence is abundant that progress in scientific discovery is particularly slow in being reflected in building and housing codes and regulations.

Even though a health department has personnel competent to develop modern standards and regulations concerning housing and its sanitation, significant constructive action to improve housing conditions is unlikely until specific information relative to local housing needs is at hand. The drafting of legislation alone cannot solve many problems in a society such as ours. Probably the most important single step that a health officer can take in the field of housing is to accumulate precise data concerning individual premises throughout the community, including the aggregation of these premises into areas significant for administrative policy and action.

Studies of administrative practices in city health departments have revealed that aimless inspection of housing brings few tangible results and does practically nothing toward the improvement of the total housing picture. For instance, in several cities relatively ambitious but inadequately directed housing inspections carried on over a long period of time have done nothing toward eliminating the poorest housing. Indeed, blight has been spreading and getting more serious, and new slums are being created despite the routine housing inspection programs. It is self-evident that the sporadic inspections which have been traditional in many urban health departments are unlikely to produce any body of actionable information.

Studies of the mechanics of complaint investigations in city health departments have revealed that many housing problems are reported by citizens.² The distribution of housing complaints in terms of time and space is spotty at best, and frequently such complaints involve no basic problems. Furthermore, routine investigations of complaints usually are directed exclusively at the situation that precipitated the complaint and ignore other aspects of the premises. Thus, the investigator frequently fails to do anything more than suggest palliative action or symptomatic treatment.

Another shortcoming of traditional housing inspections has been that they reflect the bias and personality of the inspector. It is axiomatic that individuals of dissimilar training may react differently to given sets of circumstances. Unfortunately, the forms supplied to most health department inspectors for recording and reporting are not designed to improve the objectivity of the individual. Thus, information gathered on housing conditions may be quantitatively adequate, but qualitatively almost worthless.

Because of these deficiencies in existing practice, it is likely that heroic steps will have to be taken to recast the approach to housing sanitation. In the few cities where health departments have squared with housing problems, almost without exception the initial activities have involved surveys of existing conditions.³ As a basis for developing any new health program, a careful study of what is needed has much to offer.

Certain facts that will classify the quality of existing housing are necessary if an action program is to be developed. It is essential to know which areas meet accepted minimum standards of dwelling and environmental quality. There should be information about areas showing early or moderately advanced

blight, where it would be possible economically to restore both the dwellings and environment to an acceptable minimum standard by enforcement of suitable legislation. Areas should be delimited in which the quality of dwellings or environment, or both, is so bad that it would be foolhardy to attempt to rehabilitate either for housing purposes.

In a well rounded survey, it would be expected that descriptive as well as qualitative information on familial and structural characteristics would be assembled. For instance, data on family size, dwelling unit size, and types of housing structures are essential in planning for rehabilitation and new construction.

There invariably needs to be replanning of areas in which enforcement is not sensible. Comprehensive and specific information relative to the entire local housing problem is basic to the development of an urban plan.⁴ Planners deal with neighborhoods. The quality of existing neighborhoods is determined in large measure by summing the quality of individual pieces of property. Experience has shown that subjective impressions gained haphazardly are not satisfactory for planning purposes. Without facts gathered objectively, it is impossible to plan intelligently. A survey properly organized and wisely directed will furnish the facts that are needed for planning purposes.

Pertinent local housing legislation is the backbone of a real enforcement program.⁵ Sensible legislation can be developed only if there is an understanding of the basic elements of design, maintenance, and occupancy. Local characteristics play such an important rôle in the development of ordinances and regulations that it is unlikely that standard housing codes developed by national groups can ever have specific validity everywhere. A local housing survey would be expected to provide informa-

tion that would strengthen any existing codes, and that would form the basis for amending realistically any suggested standard codes.

Health officers and sanitary engineers frequently ask if a housing survey can be done on the basis of routine inspections or complaint investigations. The answer to that question depends to a large extent on local conditions. The most economical method of carrying on a housing survey is to conduct it as a specific job with systematic coverage of significant areas. It is difficult to build up a body of useful information based on a routine, haphazard inspection program. In addition, unless actionable areas are specifically mapped out in detail and information about them is collected within a short period of time, the accumulation of data necessary to plan a program may take so long that conditions will change before there is any programmed action. The condition of housing is never static. In general, it would seem advisable, wherever possible, to carry on a survey as an intensive job and not to dilute an appraisal with other more routine activities.

The Committee on the Hygiene of Housing of the A.P.H.A., after several years of thorough study, has developed an appraisal technic for the objective measurement of the quality of urban housing.^{6, 7} This system is designed precisely to meet the needs outlined above. The method deals with structural, dwelling unit, and environmental items that are of health significance. It now has been used officially in several cities including Portland, Me., New Haven, Conn., Milwaukee, and Los Angeles, and it will be utilized widely elsewhere in the immediate future. There no longer can be doubt as to the validity of this tool for general urban use, regardless of geographic, climatic, or cultural differences that may exist between the New England communities where it was developed and cities in

other parts of the country. The primary value of this method centers around its objectivity. Subjective data are practically impossible to use in a large program. The appraisal technic substantially eliminates subjective evaluation of premises being inspected.

Users of the technic have been impressed with its completeness as well as its objectivity. With this one tool it is possible:

1. To evaluate the relative quality of the environment, the structure, and the dwelling unit.
2. To reveal substandardness of dwellings in terms of facilities, maintenance, and occupancy conditions.
3. To measure these deficiencies by scoring on an arithmetic scale of penalty points, and thus compare housing quality within and between communities.
4. To focus attention on basic deficiencies of singular health importance while, at the same time, describing minor and less important defects that in the aggregate are of public health significance.

Negotiations are in process between the Sanitary Engineering Division of the Public Health Service and the Technical Staff of the Committee on the Hygiene of Housing relative to means of facilitating the use of this technic by local officials who wish to use it. It is hoped that within the foreseeable future specially trained personnel from the Public Health Service will be available to state and local health officials to assist them in organizing local housing studies. In the meantime, the staff of the Committee on the Hygiene of Housing is available on a consultant basis to assist in setting up studies utilizing the new appraisal technic.

Success in any endeavor is not happenstance. Rather it is the result of planned application of known facts. The solution of the basic housing problem in this country is not to be found in the indiscriminate building of a tremendous number of dwellings. If we are agreed that one-third of the population is ill-housed, then we are faced with the fact that 15 million families need better housing. At present it would cost (at \$1,200 per room) at least 90 billion dollars to provide enough new housing to meet this immediate need. To be realistic, it is unlikely that this much money will be spent for new dwellings during the next quarter of a century. It is essential, therefore, that a major part of the existing housing supply be rehabilitated and preserved if every American is to have satisfactory shelter within the foreseeable future. Do you or does anyone else in your community now know with reasonable exactness which houses should be torn down and which neighborhoods can be preserved?

Microbiology of Spray-dried Whole Egg

II. Incidence and Types of Salmonella * †

MATHILDE SOLOWEY, PH.D., AND
VERNON H. McFARLANE, PH.D.

E. H. SPAULDING, PH.D., AND CECILIA CHERMERDA

*Department of Bacteriology and Immunology, Temple University School of
Medicine, Philadelphia, Pa.*

EARLY in 1942, the British Food Mission called attention to the fact that Salmonella were being isolated from dried egg powder received in the British Isles for food purposes. It emphasized the undesirability of such contamination in a food product. The British findings, however, were limited and restricted. In 1943, Seligmann, Saphra and Wassermann¹ reported the isolation of *Salmonella senftenberg* from a sample of egg powder. In the same year, Gibbons and Moore² reported the isolation of 9 types of Salmonella from Canadian spray-dried whole egg powder. This meager background of information made it clear that an investigation into the nature and extent of Salmonella contamination in dried egg should be undertaken.

The incidence and types of Salmonella found in spray-dried whole egg powder manufactured in the United States between September 1, 1943, and

January 1, 1945, are presented in this paper. This is the second one dealing with the microbiology of powder having a high moisture content (4 to 6 per cent) and involving the same series of samples. U. S. Department of Agriculture and War Food Administration purchase specifications regulating the manufacture of powder for Lend-Lease shipment and the collection of samples for microbiological analyses have been cited previously.³

METHODS

Several procedures were tried for the isolation of Salmonella in egg powder, and the one described below was adopted for the major portion of the investigation.

Twenty-five and 50 ml. of a 1:10 dilution of egg powder (11 gm. in 99 ml. saline) were each introduced into 50 ml. of Selenite-F (B-B-L) enrichment broth and incubated for 18 to 24 hours at 37° C. Each dilution was then streaked out on three selective plate media: Shigella-Salmonella (SS) agar (Difco), bismuth sulfite agar (Difco), and desoxycholate-citrate agar (B-B-L). After 18 to 24 hours' incubation at 37° C. on the selective media, characteristic

TABLE 1
Incidence of *Salmonella* in Spray-dried Whole Egg Powder

Number samples contributed by each plant	Number plants contributing samples	Number samples examined	Number samples positive for <i>Salmonella</i>	Per cent samples positive for <i>Salmonella</i>	Range of <i>Salmonella</i> types isolated per plant
1-25	45	518	164	31.7	0-7
26-50	30	1,098	338	30.8	1-11
51 or more	25	3,582	1,308	36.5	3-27
Total	100	5,198	1,810	34.8	0-27

single colonies of suspected *Salmonella* were transferred to tryptose broth. Kligler's Iron Agar (Difco) slants were inoculated from the 18 to 24 hour (37° C.) tryptose broth cultures. Those cultures characteristic of *Salmonella* on Kligler's were purified, and selected colonies were transferred to tryptose agar slants for maintenance of stock.

Although hydrogen sulfide production in Kligler's was one of the primary criteria for the preliminary identification of *Salmonella*, follow-ups were made on cultures which appeared to be *Salmonella* but apparently produced little or no hydrogen sulfide. Such organisms are comparatively rare; nevertheless several strains of *S. senftenberg* which produced no hydrogen sulfide were isolated.

From the tryptose agar slants, further tests required to confirm the preliminary identification of *Salmonella* were made, namely, motility (semi-solid agar and hanging drop), production of hydrogen sulfide and indol, liquefaction of gelatin, and the fermentation of lactose, sucrose, dextrose, salicin, maltose, mannitol, arabinose, xylose, inositol, and sorbitol. Cultures giving the characteristic biochemical reactions were tested for the "O" antigens (B, C₁, C₂, D, E). Final identification was based on the reactions of the antigenic components with known sera and with the aid of the Kauffmann-White schema.^{4, 5}

RESULTS

A total of 5,198 samples of spray-dried whole egg powder were examined

for the presence of organisms belonging to the *Salmonella* group. They were forwarded from 100 dehydration plants located in 26 states. *Salmonella* were isolated from 1,810 samples (35 per cent). Five hundred and sixty-two samples (11 per cent) were positive for *Salmonella pullorum*. Ninety-five plants contributed *Salmonella*-positive samples. Five plants failed to give *Salmonella*-positive samples; these plants, however, contributed a total of only 71 samples for examination.

Incidence and Types, by Plants—Table 1 lists the number of plants contributing samples of egg powder for examination, the number of samples examined, the number and percentage of samples positive for *Salmonella*, and the number of *Salmonella* types isolated. The plants were grouped for convenience according to the number of samples examined.

Forty-five plants each contributed 1 to 25 samples. Of 518 such samples examined, 164 (32 per cent) were positive for *Salmonella*. The number of *Salmonella* types found in samples from individual plants ranged from 0 to 7. Thirty-five plants in this group forwarded samples containing *S. pullorum*. In most instances in which there were only one or two positive samples from a plant, the samples contained *S. pullorum*.

Thirty plants contributed 26 to 50 samples each for *Salmonella* examination. Of 1,098 samples examined, 338 (31 per cent) were positive for *Salmonella*. The number of types obtained

Total	3,582	1,308		

from the individual plants within this second group ranged from 1 to 11. All but 3 of the 30 plants contributed one or more samples which contained *S. pullorum*. *S. pullorum* was the only type isolated from 5 positive samples received from one plant. In contrast, 11 types were isolated from 24 positive samples received from another plant.

Twenty-five plants each contributed 51 or more samples for *Salmonella* examination. The 3,582 samples examined from plants within this third group represent 69 per cent of all the samples examined. *Salmonella* were isolated from 1,308 (37 per cent) of the samples. The number of *Salmonella* types isolated from the individual plants ranged from 3 to 27. Table 2 lists the plants within this group, the number of samples examined from each plant, the number positive for *Salmonella*, and the number and types of *Salmonella* isolated. It may be seen that each of the plants furnished one or more *pullorum*-positive samples. Eight plants—1, 18, 21, 23, 24, 25, 30, 31—had *Salmonella* contamination in less than 30 per cent of the samples.

Ten plants—5, 6, 13, 16, 17, 20, 22, 28, 40, 42—had *Salmonella* contamination in 31 to 50 per cent of the samples. In 7 plants—2, 11, 14, 19, 27, 32, 37—more than 50 per cent of the samples were contaminated with *Salmonella*.

One hundred and fourteen (71 per cent) of 160 samples from plant 27 contained *Salmonella* representing 22 types. Plant 13 contributed the largest number of samples for examination. Of 545 samples examined, 170 (31 per cent) were positive for *Salmonella*. Despite a comparatively low incidence, the largest number of *Salmonella* types (27) were isolated from samples contributed by this plant.

Incidence and Types, by Months—The percentage contamination from June through December, 1944, was greater than that for the preceding 9 month period (Table 3). The peak of the contamination (52 per cent) was reached in August–September, 1944. In general, *Salmonella*-positive samples were more frequently encountered during the warm summer months; the percentage of samples contaminated for the months of July, August, and September,

TABLE 4

Incidence of Salmonella in Spray-dried Whole Egg Powder, by U. S. Divisions

Divisions	Number plants contributing samples	Number samples examined	Samples positive for Salmonella					
			<i>S. pullorum</i>		Other types		All types	
			No.	%	No.	%	No.	%
North Atlantic - (N. Y. and Pa.)	5	91	14	15.4	6	6.6	20	22.0
East North Central (Ohio, Ind., Ill., Mich. and Wis.)	26	1,357	170	12.5	274	20.1	444	32.6
West North Central (Minn., Iowa, Mo., N. Dak., S. Dak., Nebr. and Kans.)	40	1,563	189	12.1	255	16.3	444	28.4
South Atlantic (N. Carolina)	1	41	5	12.2	0	0	5	12.2
South Central (Ky., Tenn., Ala., Miss., Ark., La., Okla. and Tex.)	24	1,873	156	8.3	611	32.6	767	40.9
Western (Colo., N. Mex. and Wash.)	4	273	28	10.3	102	37.4	130	47.7
Total	100	5,198	562	10.8	1,248	24.0	1,810	34.8

were 45, 52, and 52, respectively. *S. pullorum* contamination was high in samples examined during February (22 per cent), March (18 per cent), and April (16 per cent). No satisfactory explanation was apparent for this finding.

It is difficult to discern any parallelism in trends in 1943 and 1944 during the months of September, October, November, and December. In so far as the data go, the incidence of *Salmonella* contamination was considerably lower for these four months in 1943 than in 1944. The comparatively low percentage (12 per cent) of contamination for September, 1943, may be attributed to the fact that only one gram of powder from each sample was tested during this particular month. In all later months, 2½ and 5 gm. quantities of powder were tested.

Incidence and Types, by U. S. Divisions—Table 4 shows that the South Central and Western divisions furnished samples having the highest incidence of *Salmonella* contamination (41 and 48 per cent). It may be observed, however, that not only were fewer plants located in the North Atlantic, South Atlantic, and Western divisions, but also fewer samples of powder were examined from

these areas. The findings, therefore, do not adequately reflect the quality of the eggs processed or the operations of plants located in these divisions.

Incidence, by Age of Samples—The number and percentage of *Salmonella*-positive samples are arranged in Table 5 according to the age (in days) of the samples. No appreciable effect of age, up through 17 days, on the incidence of *Salmonella* could be observed. Of 124

TABLE 5

Incidence of Salmonella in Spray-dried Whole Egg Powder, According to Age of Samples

Age (days)	Number samples examined	Samples positive for Salmonella	
		No.	%
2	10	1	10.0
3	49	18	36.7
4	164	60	36.6
5	391	136	34.8
6	694	254	36.6
7	822	277	33.7
8	656	238	36.3
9	536	172	32.1
10	442	160	36.2
11	367	113	30.8
12	256	96	37.5
13	183	54	29.5
14	97	21	21.7
15	45	19	42.2
16	54	22	40.7
17	50	19	38.0

samples of powder of various ages between 18 and 43 days, 35 (28 per cent) were positive for *Salmonella*. It would seem, therefore, that death of *Salmonella* organisms in egg powder is slower than might be expected.

teen hundred and sixty-nine isolations of *Salmonella* were made from 1,810 positive powder samples. These isolations yielded 52 *Salmonella* types, which are listed in Table 6 according to frequency of distribution. Five types, *S. pullorum*, *S. oranienburg*, *S. montevideo*, *S. tennessee*, and *S. anatum*, comprised 73 per cent of the total isolations. The next 10 types in order of frequency comprised 19 per cent of the total isolations, and the remaining 37 types 8 per cent.

The numbers of *Salmonella* isolations and types in each antigenic group are given in Table 7. The largest number of isolations, 829 (42 per cent), were members of the C₁ group, the next largest number, 570 (29 per cent), were members of the D group, followed by groups E₁, B, C₂, E₂, E₃ and F (further groups), respectively. The number in the B group was surprisingly low. Although *S. typhimurium* was the most commonly isolated member of this group, it was only seventh in the frequency distribution of the types isolated from egg powder (Table 6). Ninety-five per cent of the isolations fell within the 5 basic antigenic groups (B, C₁, C₂, D, E).

In Table 8 the distribution of *Salmonella* types isolated from spray-dried whole egg with a high moisture content in this study and from egg and egg products in field studies⁶ is compared with

TABLE 7

Frequency of Isolation of Salmonella Types from Spray-dried Whole Egg Powder, Tabulated by Antigenic Groups

*F = Further groups

the distribution of types found in human, poultry, and animal infections as reported by Edwards and Bruner⁷ and Seligmann, Saphra, and Wassermann.¹ Edwards and Bruner's survey was based on the analyses of 3,090 cultures of *Salmonella* isolated from 2,285 outbreaks in man, poultry, and animals in the United States between 1934 and 1941. Seligmann, Saphra, and Wassermann analyzed 1,000 cases of human *Salmonella* infections (not including *Salmonella typhi*) identified and studied in the period between 1939 and 1943. With the exception of *Salmonella paratyphi* A, only the *Salmonella* types isolated from spray-dried whole egg in this study (MRD)* are listed in the table. The frequency of isolation of each type is recorded for egg and non-egg studies. Types found in non-egg studies but not in egg powder have been listed in each group as "others."

Table 8 shows that many of the *Salmonella* types found in egg powder are identical with types isolated from animal, poultry, and human sources. The majority of the types reported in the non-egg studies are among those reported in the dried egg study (MRD), that is, 38 of the 59 types identified at the Lexington Center,† and 26 of the 38 types identified at the New York City Center.‡ It may further be observed that the types isolated with greatest frequency in any one of the studies are in most instances common to the others.

Group A—*S. paratyphi* A, the only type in Group A, was not isolated from egg powder. Presumably it is one of the few types which have exhibited a greater adaptation for the human host. Aside from *S. typhi*, the majority of the types in the other groups usually give rise to

gastroenteritis (food poisoning), but as Seligmann, *et al.*¹ have stated "every *Salmonella* is potentially capable of producing every one of these groups of clinical processes," that is, gastroenteritis, localized processes, typhoid-like symptoms, and symptoms of septicemia without localizing signs, fatalities, and the asymptomatic carrier state.

Group B—Five per cent of the isolations from egg powder (MRD) belonged to Group B. *S. typhimurium* was the most frequently encountered of the 11 types within this group and made up 3 per cent of the identified cultures. *S. typhimurium* was the only member of Group B reported in Canadian egg powder.² Group B isolations were considerably higher in the non-egg studies, 43 per cent and 49 per cent, respectively. Again, *S. typhimurium* was largely responsible for these high percentages. It made up 27 per cent of the Lexington Center's isolations⁷ and 37 per cent of the New York City Center's isolations.¹ *S. derby* and *S. paratyphi* B were also isolated more frequently from animals, poultry, and humans than from egg powder.^{7, 1}

Group C ($C_1 + C_2$)—Approximately 45 per cent of the typed cultures from egg powder (MRD) belonged to the C group. This is the major group in so far as the dried egg findings are concerned. Although 16 types were identified, 5 types—*S. oranienburg*, *S. montevideo*, *S. tennessee*, and *S. bareilly* of subgroup C_1 and *S. newport* of subgroup C_2 —comprised 43 per cent of the identified cultures. The relatively high distribution of these 5 types in the Lexington survey may probably be explained by the fact that it included numerous isolations from poultry and animals. With the exception of *S. newport*, they were less frequently encountered in man. *S. newport* was encountered in 3 and 9 per cent of the isolations in both non-egg studies. *S. choleraesuis* and *S. choleraesuis* var. *kunzendorf* were isolated with

†Per cent of total isolations.

great frequency only in the non-egg studies.

Group D—Three D types made up 29 per cent of the dried egg isolations (MRD). The D group, which is the second largest for dried eggs, owes its size to the number of isolations of *S. pullorum*. A similarly large percentage for this group (24 per cent) was reported in the Lexington survey. *S. pullorum* owes its prominence in the dried egg and Lexington studies to the fact that it is primarily a poultry pathogen. It has

been encountered in man, however.⁷⁻⁹ The total D isolations for the New York City Center was 7 per cent, a figure decidedly lower than that reported for the other studies.

Group E ($E_1 + E_2 + E_3$)—Sixteen per cent of the dried egg isolations (MRD), comprising 11 types, belonged to group E. Distribution reported for the Lexington and New York City Centers was 11 and 6 per cent, respectively.

Group F—Approximately 5 per cent of the dried egg isolations (MRD). com-

prising 12 types, belonged to group F. Distribution reported for the Lexington and New York City Centers was 2 and 3 per cent, respectively.

The distributions in the B, C, D, E, and F groups of the *Salmonella* isolated by Gibbons and Moore² and by Solowey, *et al.*⁶ during field studies correspond closely with the distribution found in powder having a high moisture content (Tables 7 and 8).

DISCUSSION

The investigation reported here has been of necessity limited to a qualitative study of the incidence, types, and distribution of *Salmonella* found in spray-dried whole egg. Nevertheless, it has brought out evidence that the *Salmonella* types isolated from egg powder have the same morphological and cultural characteristics and give the same biochemical and serological reactions as types isolated from infected humans.^{2, 9, 10-13} It should be kept in mind, however, that the methods used for the isolation of *Salmonella* from egg powder were not radically different from methods employed for *Salmonella* isolation from other sources. Although three selective media were used in the isolation of *Salmonella*, bismuth sulfite agar was as satisfactory as SS agar for the various *Salmonella* types, and apparently better for the isolation of *S. pullorum*. Most of the latter were isolated from bismuth sulfite agar.

The *Salmonella* contaminations reached a peak during the summer. This is in line with general information concerning the poorer quality of shell eggs marketed during this time of year. The fact that the percentages of samples contaminated during the fall were also high may be attributed, in part at least, to the use of frozen and storage shell egg liquid obtained from substandard shell eggs and/or from improperly frozen and improperly stored summer surpluses of shell eggs.

It is difficult to assess the significance of such factors as temperature, humidity, and type of soil in establishing a causal relationship with *Salmonella* contamination. Very little is known concerning the source and quality of the raw material used by the individual plants or the relative effects of different processing methods on microbial destruction. Actually, some of the plants whose samples showed a high incidence of contamination were located in areas characterized by high temperature, high total precipitation, and specific kinds of soils. However, it is not possible to attribute with exactitude the high incidence of contamination to the environmental factors cited. In order to evaluate the facts, more complete histories than those hitherto given must be made available with the samples to be examined.

The dangers arising from the consumption of raw and incompletely cooked duck eggs are well known and accepted. Adequate proof that hens' eggs may be similarly infected is still lacking. A recent direct accusation of hens' eggs in this country has been made by Watt.¹⁴ He investigated an outbreak of salmonellosis (*S. montevideo*) aboard a merchant vessel which affected 28 individuals in a crew of 70. "Epidemiological evidence indicated that infection resulted from the consumption of contaminated egg salad, the mayonnaise of which contained raw eggs. The same *Salmonella* type, *S. montevideo*, was isolated from two cases of shell eggs obtained on the ship. Internal contamination of the eggs was demonstrated, since the shell washings before sterilization were free of *S. montevideo*, and egg meats obtained after sterilization of shells were found to contain this organism."

S. pullorum is one of the types hitherto ignored to some extent in egg products for human consumption because it has always been assumed to be non-pathogenic for man. In the last

few years, however, it has been isolated from infected human beings.⁷⁻⁹ The presence of *S. pullorum* in cases of gastroenteritis is probably more widespread than is realized, but because of its fastidious growth requirements and slightly different morphological characteristics on selective media, it is not isolated from infected material with the same facility as other members of the *Salmonella* group.

There is no evidence in the data that any *Salmonella* type occurs more frequently in powder produced in one locality in the United States than in any other. Moreover, there is no evidence that any *Salmonella* type is specific to egg powder. On the other hand, the percentages of the types within the major groups appear to be different from those found for the other frequency distributions cited. It may be reasonably assumed that a similar distribution might be encountered only in the examination of poultry and poultry products.

Borman pointed out that the "number of *Salmonella* types that occur exclusively in man or animals is diminishing." This statement has been amply confirmed by the investigators cited. The pathogenicity of the strains isolated from dried egg is as yet undetermined. Various arguments have been set forth that (1) the organisms may be present in too few numbers to initiate infection, (2) they may have been attenuated by heat, and (3) contaminated powder has not been cited in the literature as a cause of *Salmonella* infections. Nevertheless, although the validity of these statements is admitted, the presence of *Salmonella* organisms in this food product constitutes a potential hazard, especially with respect to the treatment of reconstituted powder.

The presence of such a wide variety of *Salmonella* types in spray-dried whole egg powder is evidence *per se* that the drying process as utilized in the manu-

facture of high moisture (4-6 per cent) powder does not destroy the organisms. That powder of low moisture content (not exceeding 2 per cent) still contains *Salmonella* is indicated in the work of Schneider^{15, 16} who reported the isolation of five *Salmonella* types, *S. pullorum*, *S. oranienburg*, *S. tennessee*, *S. oregon*, and *S. montevidео*, from samples of such powder. Our own investigations of low-moisture powder (unpublished data) indicate that *Salmonella* are not entirely eliminated.

SUMMARY

Salmonella were isolated from 35 per cent of 5,198 samples of spray-dried whole egg powder obtained from 100 dehydration plants between September, 1943, and January, 1945. Incidence of *Salmonella* in samples examined from individual plants ranged from 0 to 71 per cent. Fifty-two *Salmonella* types were identified, five of which, *S. pullorum*, *S. oranienburg*, *S. montevidео*, *S. tennessee*, and *S. anatum*, made up 73 per cent of the isolations. Culturally, morphologically, biochemically, and serologically the 52 types are in every way similar to those isolated from human beings and animals. The types that occur with greater frequency in dried eggs are among those that commonly occur in human and animal infections. The frequency distribution of the *Salmonella* types isolated from dried eggs is not the same as that of the types isolated from human beings.

Proposed National Heart Disease Institute

On June 9, Congressman Javits of New York, introduced a bill in the United States Congress providing for the creation of a National Heart Disease Institute within the U. S. Public Health Service. Such an institute would provide for research and the development of more effective methods of prevention, diagnosis, and treatment of the diseases

of the heart and circulation. The bill was referred to the Committee on Interstate and Foreign Commerce.

The Board of Directors of the American Heart Association unanimously approved the bill at a meeting held in conjunction with the 23rd annual meeting of the Association in Atlantic City in June.

Shellfish*

Engineering Section

THE Shellfish Committee of the Engineering Section met in New York City on the morning of June 4, 1946. A joint luncheon and afternoon meeting was held on this same date with the Committee on Standard Methods for the Examination of Shellfish. This was the first meeting of the committee in two years, because of travel restrictions in 1945.

Since the time of the last meeting the Public Health Service has adopted and placed in operation the new *Manual of Recommended Practice for the Sanitary Control of the Shellfish Industry*. Much of the discussion at the 1946 meeting therefore had to do with this *Manual*. In reporting on these subjects the same order will be followed as that occurring in the *Manual*. Reference numbers where used refer to *Manual* numbers. In addition to the discussion of the *Manual* some other subjects were considered. These included recent food and drug activities and some new developments within the industry.

U. S. PUBLIC HEALTH SERVICE MANUAL OF RECOMMENDED PRACTICE FOR THE SANITARY CONTROL OF THE SHELLFISH INDUSTRY

Definitions (1)—The committee was of the opinion that in view of the rapid development of some quick frozen foods, using raw or partially cooked shellfish, the definition of "shellfish" appearing on page 5 should be revised. It is

recommended that this definition be changed to read as follows:

Shellfish: Shellfish means all fresh or frozen oysters, clams, or mussels either shucked or in the shell, and any fresh or frozen or incompletely sterilized edible products thereof.

It is apparent from the above recommendation that the committee believes that the frozen food industry handling shellfish products should be under the same sanitary supervision and control as the fresh or unprocessed shellfish industry. Processed or canned shellfish, where the processing or canning results in a sterile product, have always been exempt from the control of the Public Health Service and are the responsibility of the Food and Drug Administration. Likewise, where frozen foods contain completely processed or sterilized shellfish products before freezing, such frozen foods will become exclusively the responsibility of the Food and Drug Administration. The Public Health Service and the State Regulatory Authorities responsible for fresh shellfish sanitation will, however, be responsible for frozen foods containing raw or partially cooked shellfish.

BACTERIOLOGICAL EXAMINATION OF SHELLFISH AND SHELLFISH WATERS

(3.3)—As indicated in the opening paragraph, the Engineering committee met jointly with the Laboratory committee to consider some problems com-

* Progress Report of the Committee on Shellfish.
Committee on SHELLFISH (Engineering Section)

Organized 1928 Published reports: *Year Books* 1934-1935, 1935-1936, 1936-1937, 1937-1938, 1938-1939, 1939-1940, 1940-1941, *A.J.P.H.*, July, 1941, July, 1945

mon to both. During the morning the Laboratory committee had held a separate meeting. It is believed that some revisions in the recently adopted "Standard Methods" for the examination of shellfish and shellfish waters are contemplated as a result of these meetings. Basically, however, the methods will remain unchanged. It was the opinion of the joint committees, however, that the limiting standards set forth in the *Manual* were not satisfactory and should be changed as quickly as possible. No conclusions could be reached at the June meetings as to how they should be changed.

This matter of satisfactory and suitable limiting standards for the sanitary quality of shellfish and shellfish waters has always been a troublesome problem. There seems to be a general agreement on the limiting bacteriological standards for the quality of shellfish waters, although even this is not unanimous. But when the question of limiting bacteriological standards for shellfish is considered, there seems to be little if any agreement. Now, with the added problem of setting up practical standards for frozen shellfish and shellfish products, the question of standards becomes even more complex. The joint committees realize the extent of this problem and have decided to meet again in Cleveland for further discussion of this particular subject. It is hoped that out of this meeting there will be developed some reasonable, practicable and much needed bacteriological standards for the shellfish industry.

Cleansing (4.2)—Although this subject was not discussed at the meeting, nevertheless it is desirable that the committee carefully consider recent developments by the Fish and Wildlife Service which indicate that some of our former concepts on this subject may be in need of revision. This may also be true in the case of *Floating* (4.5).

Bactericidal Treatment (4.21)—It is

often difficult to get a sufficient supply of hot water or live steam in shucking and packing plants to insure sterilization of equipment. Recently a new piece of equipment has been tried to overcome this difficulty. This equipment is used extensively in garages for cleaning motors. It is a kerosene burner that produces an almost instantaneous and continuous stream of steam under pressure. The machine is small, compact, and portable. It requires only connections to a water supply and an electric outlet. Various lengths of steam hose and several types of nozzles come with the machine. Final tests of the efficiency of this machine have not yet been made, but its use under certain conditions seems promising.

Shipping Containers (4.29) — The post-war development of air transport for shellfish and the expanded frozen food activities will bring about new and as yet untried shipping containers. Some firms have already been experimenting with pliofilm packages. In any event the more extensive use of individual consumer packages appears to be in the offing. The committee welcomes this development and believes it should encourage the use of such packages in the interest of giving the consumer better shellfish.

The proper identification of such consumer packages containing fresh or frozen shellfish does not seem to be fully covered in the *Manual*. It is the committee's recommendation that such packages should show clearly on their labels the following information:

1. The name and address of the packer or distributor.
2. A statement of the true contents of the package.
3. The certificate number of the shucker or packer, preceded by state abbreviations.
4. The date of packing. This may be in code and such a coding should have some reference to the lot packed which would show upon examination of the records of the packer the source of such shellfish and date shucked.

Packing and Shipping Shell Stock (4.39)—In the mussel producing areas some difficulty has been experienced in obtaining a satisfactory shipping container. The use of burlap bags commonly used in the shipment of other types of shellfish is unsatisfactory for mussels. Mussels begin to drain rapidly soon after removal from the water and this drainage is soaked up by such bags resulting in increased growths of bacteria which are in turn further drained into lower layers of the mussels. Mussels showing satisfactory concentrations of bacteria when taken from good areas are therefore quite often found to contain excessive bacteria when they reach the market. This is particularly true in warm weather. It is recommended that the use of such bags in the shipment of mussels be prohibited.

Identification of Shell Stock on the Market (4.40)—As required in the *Manual*, shell stock should bear a tag on each container showing:

1. The name and address of the shipper with his state certificate number preceded by the state abbreviation.
2. The name and address of the consignee.
3. A statement of the kind and quantity of shellfish in the container.
4. The date of shipment, coded or un-coded.

In addition to these items the committee believes such tags should show the *source* of such shellfish. This information should be tied down to as small an area as possible.

NEW MACHINES FOR SHUCKING OYSTERS

During the meetings of the committee and the later meetings of the Oyster Institute, demonstrations were given of two recently developed machines for the mechanical opening of oysters. One of these machines shears the adductor muscle from one shell and leaves the oyster attached to the other shell. The second machine operates very much the same as the mechanical potato peeler.

It would not seem that either machine at this stage of development could replace the hand opening in commercial shucking plants, but the shearing machine might be useful in opening oysters for laboratory examination. Either machine would be helpful in the opening of oysters in restaurants for half shell trade.

PROCESSED OR CANNED SHELLFISH

Although the Public Health Service is not concerned with processed or canned shellfish because these products come under the Food and Drug Administration, nevertheless, the committee believes that only shellfish of good sanitary quality should be used in such packages. It is desirable to have such containers bear some lot or code number which would permit the tracing of their contents to their origin.

USE OF SHELL LIQUOR

From time to time attempts have been made by some packers to save and process or sell shell liquor drained from shellfish during the opening process. The committee is of the opinion that while such a practice might meet the requirements of the *Manual*, it is more than likely it would not and therefore it should be discouraged. If, however, such a practice is undertaken it is thought that the Food and Drug Administration must define its limitations. In such cases consideration should also be given to the pasteurization of such liquors.

FOOD AND DRUG ADMINISTRATION

Activities of the Food and Drug Administration were outlined for the committees by Glen D. Slocum with particular reference to the proposed establishment of standards of identity. These standards are being established for the purpose of:

1. Decreasing to a minimum the time the shellfish are in contact with fresh water.

2. Assuring adequate drainage after washing.
3. Obtaining uniform sizes for consumer protection.

It will be noted that such standards of identity have already been established and go into effect on January 1, 1947.

IMPORTATION OF SHELLFISH

Although the listing of Canadian shippers by the U. S. Public Health Service was discontinued some years ago there has been no satisfactory substitute provided by any federal agency. Many foreign countries are trying to ship shellfish into this country, and there fails to exist today any legal means for accepting such shipments other than the "after arrival" procedure of the Food and Drug Administration. From a public health point of view such a procedure is unsatisfactory. The committee recommends that the Public Health Service investigate the possibility of once more arranging for the listing of the shippers of such countries as may carry out a control program at the source of supply comparable with our program in this country. It has been suggested that such a program might become a function of the World Health Organization.

SCORE SHEETS

The committee believes that a satisfactory score sheet for the evaluation of both shellfish plants and state control measures has not yet been developed, and would welcome suggested sheets for future consideration.

GENERAL COMMITTEE RECOMMENDATION

The committee endorses the new Public Health Service *Manual* in principle

and recommends that the Public Health Service extend, if possible, its shellfish sanitation program along three principal lines of endeavor as follows:

1. Provide for a full-time sanitary engineer to engage in shellfish sanitation work in each district.
2. Provide for continuous research and technical study of shellfish sanitation problems.
3. Stimulate or carry out some effective educational program in the consuming areas for the purpose of eliminating unsatisfactory practices, particularly on the part of retailers.

ADDENDUM

The joint committee meeting took place in Cleveland on November 11, 1946. The following were agreed upon:

1. That within the limits of our present knowledge the procedure outlined in the *Manual* for determining classes of shellfish areas based on sanitary surveys and coliform results is generally satisfactory.
2. That any recommended changes in limiting bacteriological standards for shellfish or shellfish products must be based on factual data.
3. That such factual data are not available and, consequently, no changes are now being recommended for shellfish standards although the committees believe that the shellfish standards now appearing in the *Manual* are inadequate and must be revised as soon as factual data permit.

Cheese and Its Relation to Disease*

F. W. FABIAN, PH.D., F.A.P.H.A.

Professor of Bacteriology and Public Health, Department of Bacteriology and Public Health, Michigan State College, East Lansing, Mich.

CHEESE is a standard item of diet and rates very high among foods from a nutritive standpoint. It is therefore important that it should be surrounded with all the necessary sanitary safeguards to insure a product free of disease germs. Cheese like other dairy products such as ice cream and butter does not receive the attention from public health officials that it merits. However, the long list of epidemics of disease traced to it¹² within recent years has awakened those responsible for the health of the people to the need of sanitary regulations governing its manufacture and sale.

EPIDEMICS TRACED TO CHEESE

A list of epidemics traced to cheese since 1883 has been compiled from the literature and various other sources and is presented in Table 1. A summary of these data shows that during this time there has been a total of 59 epidemics with 2,904 cases of disease and 117 deaths. While this total is sufficiently impressive to convince even the most skeptical, there is every reason to believe that this represents only a fraction of the total. After the epidemics reported by Baker¹ in Michigan during 1883-1884, there were no more epidemics recorded until 1893, after which there was a lapse of 21 years before

another epidemic was reported. Thereafter, only an occasional epidemic due to cheese was reported in the literature until 1932 when the big epidemic occurred in Quebec with 627 cases and 57 deaths. This epidemic seems to have made public health officials conscious of the fact that cheese may be an important vehicle for the transmission of disease, and from that time on we find one or more epidemics reported each year except in 1933.

From 1935 to 1945, 40 epidemics were reported involving 1,741 cases and 47 deaths, which is over twice as many epidemics as the 19 which were reported in the previous 42 years. Such figures as these lead one to suspect strongly that during this time cheese had been overlooked as a source of disease.

While no attempt has been made to make a thorough search of the foreign literature for epidemics due to cheese, a partial list of such epidemics is recorded in Table 2. From 1901 to 1944 inclusive, 16 epidemics involving 526 cases and 2 deaths have been tabulated.

An analysis of the data in Table 1 shows that the most frequently reported disease is food poisoning which accounted for 35, or 61 per cent, of the 59 epidemics with 1,389 cases, or 47.9 per cent of the total 2,904 cases reported. Next in order comes typhoid fever with 16, or 27 per cent of the total number of epidemics. Although typhoid fever was responsible for only 27 per cent of the epidemics, it accounted for 1,354, or 46.6 per cent of the total

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946.

TABLE 1
Outbreaks of Disease Traced to Cheese in the United States and Canada from 1883 to 1946

Disease	Place	Date	Cases	Deaths	Kind of Cheese	Reference	Remarks
Food poisoning	Hubbardston and Oxford, Mich.	Aug., 1883	14-15	0	Cheddar	Baker ¹	Cheese made in Ohio.
Food poisoning	Middleville, Mich.	May, 1884	50-60	—	"	Baker ¹	New cheese made by Horton at Fruitville, Mich.
Food poisoning	Jerome, Mich.	June, 1884	24+	—	"	Baker ¹	" " " " " "
Food poisoning	Jonasville, Mich.	June, 1884	10	—	"	Baker ¹	" " " " " "
Food poisoning	Flint, Mich.	June, 1884	4	—	"	Baker ¹	Cheese believed made at Clio, Mich.
Food poisoning	Big Rapids, Mich.	July 1, 1884	30	—	"	Baker ¹	Cheese made at one of the factories of Horton.
Food poisoning	Carson City, Mich.	July 8-9, 1884	13	—	"	Baker ¹	Cheese made by Horton at Fruitville, Mich.
Food poisoning	Lowell, Mich.	Aug. 28, 1884	13	—	"	Baker ¹	Origin of Cheese not determined.
Food poisoning	Mansfield, Ohio	1893	Many cases	—	Cheese	Reed ²¹	Tyrotovicon. Spoiled milk used for making cheese. Also two sick cows found among those supplying the milk.
Botulism	New York State	Oct., 1911	3	3	Cottage (homemade)	Nevin & Mann ²¹ Also Nevin ²⁰	Organisms and their filtrates toxic to mice, guinea pigs and rabbits.
Food poisoning	Kalamazoo, Mich.	June 20, 1916	6	—	Cheddar	Levine ²⁴	Coliform organism but poison was soluble and thermostable.
Typhoid fever	Bath township, Mich.	1917	51	4	"	Rich ²⁷	Cheese made at Chesaning, Mich., sold 9 to 30 days after it was made. Believed to be due to a typhoid carrier on farm.
Typhoid fever	4 counties	Feb., Mar., Apr., 1925	29	4	"	Wade & Shore ²¹	Infection came from cheese made at Cooperative Creamery. Cheese sold 10 days after milking. Typhoid carrier on farm delivering milk to creamery.
Food poisoning	Bedford, Me.	1925	9	0	Albanian cheese	Linden, Turner & Thom ²¹	Large numbers of cocci present. Cultured organisms when fed to rats produced diarrhea within 4 hours.
Food poisoning	Kansas City	1926	22	0	Cheddar	Linden, Turner & Thom ²⁷	Large numbers of cocci present which were morphologically and culturally similar to those isolated from the Albanian cheese.
Food poisoning	U.S.S. Ruben James	1926	20 40	0	Cheese	Thomas & Carl ⁴⁹	Cheese part of 1,400 lb. lot procured in New York City. No evidence of Salmonella group.
Food poisoning	Apparently Ontario	1929	130+	0	Probably cheese	Hardman & McKinnon ²¹	Outbreak believed to have been due to cheese served at church social. Others who had eaten of same cheese purchased at grocers became ill.
Typhoid fever	St. Maurice Valley, Que.	1932	627	57	Canadian cheese	Foley ¹⁴	Cheese made from unpasteurized milk which was taken from several producers in whose families there were cases of typhoid fever.

CHEESE

Disease	Locality	Year	No. of cases	No. of deaths	Cottage cheese	U.S.P.H. ⁵⁰	Cottage cheese made from raw milk.
Typhoid fever	Parkersburg, W. Va.	1931	24	51	Wisconsin cheese	Dunderson ⁶ Also U.S.P.H. ⁵⁰	Green producing colonies of streptococci which were slightly hemolytic were reported by the laboratory. Women who had eaten the cheese in the town where it was manufactured also were ill. "Gastroenteritis was no doubt due to saprophytic organisms rather than dysentery bacilli." Cheese made from pasteurized milk.
Food poisoning	Chicago, Ill.	1935	0	0			
Gastroenteritis	Whiting, Ind.	1935	8	0	Cream cheese	McCarthy ²³	
Food poisoning	Idaho	1935	12	0	Cheddar	U.S.P.H. ⁵⁰	
Typhoid fever	Thorsby, Calgary, Edmonton, Can.	1936	22	4	Bow ³	Staphylococcus albus isolated. Cheese made from raw and pasteurized milk. Unpasteurized cream Staphylococcus aureus isolated.
Food poisoning	Mapleton, Minn.	1937	37	0	Cottage	U.S.P.H. ⁵⁰	
Food poisoning	Sunnyside, Wash. Chicago, Ill.	1937	6	0	Cheddar	U.S.P.H. ⁵⁰	
Diarrhea	Chicago, Ill.	1937	11	0	Imported Romano	U.S.P.H. ⁵⁰	
Typhoid fever	Thorsby, Alberta, Can.	1938	24	0	Imported Pecorina	U.S.P.H. ⁵⁰	Raw milk used in making cheese. Fecal contamination present. Tyrotoxin suspected. A case of botulism. Cheese prepared June 5 to 8 and consumed by 3 persons June 9 and 10. 225 persons ate cheese from local factory at church supper. Estimated that 500-700 persons ate cheese from same factory and from 100-200 became ill. Staphylococcus aureus. Cheese made from raw milk. Cheese was not aged.

number of cases of disease and for 97.4 per cent of the total number of deaths. There were 4 epidemics listed as causing gastroenteritis, 2 as causing diarrhea, and 2 as causing botulism, with a 50 per cent mortality. In the case of typhoid fever there was approximately 1 death for every 12 cases of the disease, which would indicate that the typhoid organism remained viable and virulent in cheese sufficiently long to cause severe infection. In contrast to the high mortality for typhoid fever there was not a single death reported in the 1,389 cases of food poisoning due to cheese, indicating that the organisms responsible for this condition either did not produce a potent toxin or else did not remain viable sufficiently long to cause a severe infection or to produce enough toxin to cause death.

The most recent epidemic of typhoid fever traced to cheese was at Cornwall, Ontario, in January and February, 1946. Since this epidemic has not been reported in the literature, the details as reported by Dr. M. G. Thomson, Medical Health Officer⁴⁶ at Cornwall, will be given.

Between 26th January and 25th February, 1946, nineteen cases of typhoid fever occurred in the City of Cornwall and the surrounding suburban area which were traced to two cheeses from one cheese factory and the carrier discovered some weeks later. After the fourth case was reported there was presumptive evidence that cheese purchased in two grocery stores was implicated. It was ascertained that one cheese in each store (which had been already sold so that no sample was available for bacteriological testing) was out, contrary to Dominion of Canada Food Regulations, within the ninety day holding period prescribed by those Regulations. These two cheeses were from the same factory and it soon became necessary to find the carrier who infected the milk which went into those two cheeses. This was simplified owing to a case of typhoid fever occurring in the area supplying milk to the cheese factory in question. The patient had been on a visit to his mother and she was found to be a carrier of typhoid fever. Milk from the farm operated by

this woman had gone into the manufacture of the two cheeses in question which constituted one batch and these were the only cheeses from this factory which had been released to the retail grocers within the ninety day holding period prescribed by the Dominion Government Food Regulations. I may say that on investigating other milk producers whose milk went into the two cheeses in question, no other carriers were found.

I may say that stool specimens from all the possible food handlers in the grocery stores in question were all negative for *E. typhosa* though these tests were repeatedly done.

The organism in all the cases in this outbreak as well as in the stool specimens from the carrier was *E. typhosa*, Type E.

HOW TO PREVENT DISEASE FROM CHEESE

Two things stand out when a study is made of the various epidemics caused by cheese. One is that the cheese generally has been made from raw milk and that it has been sold and eaten too quickly after it has been made. Likewise, in the experiments testing the longevity of pathogens in cheese the data show that pathogenic bacteria die out more quickly at high than at low temperatures.* This leads to the obvious conclusion that all milk and cream used in the manufacture of cheese should be pasteurized and aged at a high temperature. If this were done, the transmission of disease by eating cheese would disappear.

PASTEURIZING AND AGING CHEESE

Pioneer work for using pasteurized milk for cheese making was done in 1912 by Sammis and Bruhn³⁸ in Wisconsin. The following paragraph from their *Research Bulletin 27* is especially significant in view of the many cases of disease traced to cheese since that time:

This process should interest the farmer because of the increased yield of cheese, and the avoidance of the usual losses in yield and quality due to defective milk. It should interest the cheese maker because the process of making is systematized to such a degree that it is conducted upon a fixed schedule for

TABLE 2
Outbreaks of Disease Traced to Cheese in Other Countries

Disease	Place	Date	Cases	Deaths	Kind of Cheese	Reference	Remarks
Food poisoning	Finbury	Oct., 1901	17	—	Dutch cheese	Newman ²²	Laboratory examination revealed a "poisonous tomatine."

Food poisoning	Reig prison	1936	100 25 others	0	White cheese	Kathe ²¹	Blood of 7 patients agglutinated a hemolytic strain of hemolytic coli in dilutions as high as 1:1,600.
Food poisoning	France	1938	3	—	Pont L'Eveque	Florentin ¹²	3 persons in a family of 4 ate the cheese and became ill. The other member who was not ill did not eat the cheese.
Food poisoning	Magdeburg, Germany	1938	28 4 others	—	Limburger	Schade ¹⁰	Strain of <i>B. coli</i> isolated from cheese produced poisonous symptoms in mice.
Brucellosis	Eritrea, Italy	1943	Several	0	Cheese	Cilli ⁷	Undulant fever traced to cheese containing <i>Brucella melitensis</i> . Cheese made from cow's, goat's, and sheep's milk.
Food poisoning	Norwich, England	1944	4	0	Goat's milk cheese (homemade)	MacDonald ²³	<i>Staphylococcus aureus</i> isolated from one patient and from freshly drawn goat's milk.

NOTE: Since these tables were compiled, notice of two more epidemics due to cheese has been received from the U. S. Public Health Service as follows:

Food poisoning	Stinesville & Anderson, Ind.	Oct., 1945	9	0	?	Private homes
Food poisoning	Barrio Miraflores Arecibo, P.R.	Mar., 1945	17	1	Native cheese	Raw milk used

all operations. It should interest the dealer because the cheese is more uniform in quality, and there is less need for cold storage for curing. Finally, the cheese should interest the consumer because it is more uniform in flavor than most cheese to be found on the retail counters, being made from pasteurized milk; and it is a more sanitary product than ordinary American cheese made from raw milk.

One of the reasons why cheese makers have resisted pasteurization is because the technique for making cheese from pasteurized milk is somewhat different from making it from raw milk. Rogers and associates worked for years studying and perfecting cheese making from pasteurized milk. This has developed the precision or "clock" method of making cheese from pasteurized milk which includes (a) use of pasteurized milk, (b) controlled starter cultures, and (c) exact timing of each operation in cheese making. They have demonstrated⁹ that, contrary to popular belief, it is possible to make a high quality cheese more uniform in flavor from pasteurized milk. In fact they have shown that by using a good grade of milk and cream, pasteurizing and adding a starter, it is possible to age the cheese at a temperature of 60° F. instead of 40 to 50° F. thereby reducing the aging period from 6 to 8 months to 3 to 4 months. Ereksøn¹¹ points out that the higher temperature aging period was used for years but discarded because of certain disadvantages.

There are two safety factors in the pasteurized milk process of making cheese: First, pasteurization which is properly done will kill all asporogenic, pathogenic bacteria which have been responsible for so many epidemics and, second, the aging period at the higher temperature. Even though the ripening is for a shorter period of time, the higher temperature will help to kill any pathogens that may have escaped pasteurization or that have gotten into the cheese after pasteurization. All ex-

periments with cheese artificially or naturally seeded with pathogens show that the pathogens die more quickly at the higher than at the lower temperatures.

STATE AND CITY LAWS ENACTED

California in 1944 was the first state to pass a law requiring that all cheese sold to the retail trade shall be pasteurized or made from pasteurized cream, milk, or skim milk which has been pasteurized, except cheese which has been allowed to ripen or cure for a minimum period of 60 days. Further requirements are made for labeling the variety, grade, factory number, state of origin, and date of manufacture. This law resulted from an outbreak of typhoid fever caused by green cheese in which there were 79 cases in 9 counties in California and 4 in Nevada.

Colorado likewise passed a similar state law which became effective January 1, 1945, which requires that all cheese shall be pasteurized or made from pasteurized cream, milk, or skim milk, except cheese which has been allowed to ripen for a minimum period of 120 days or longer if deemed necessary. In the same year New York amended the State Sanitary Code to require that Cheddar type cheese be pasteurized or that it be made from pasteurized cream, milk, or skim milk, or had been allowed to ripen at a temperature of not less than 35° F. for a period of not less than 60 days from date of manufacture.

Canada, due to the many outbreaks of disease traced to cheese, passed a regulation which became effective August 1, 1945. This regulation among other things requires:

1. Every manufacturer of cheese by the Cheddar or other process from raw or pasteurized milk that yields a hard-pressed cheese shall mark or brand within 24 hours after removal from the press every merchandising unit of such cheese correctly and distinctly with the date of manufacture indicat-

ing the day, month, and year when such cheese was put into press.

2. No person shall cut any Cheddar or other hard-pressed cheese made from raw or pasteurized milk for sale or consumption as such in Canada within a maturing period of 90 days from the date of manufacture. Throughout the first 10 days of said maturing period of 90 days the temperature of storage shall be maintained at not less than 58° F., and throughout the remainder of the period at not less than 45° F.

Illinois amended a former act regulating the sale of dairy products on May 5, 1945, which became effective January 1, 1946. The amended act requires, among other things, that cheese be made only from pasteurized milk and cream or be ripened or cured for at least 60 days at a temperature not lower than 35° F.

Indiana likewise has amended the regulations regarding the manufacture of cheese to the effect that milk and cream used in its manufacture must be pasteurized or that cheese made from raw milk must be held for at least 60 days before it can be used or sold.

New Jersey likewise has recently passed regulations regarding the manufacture and sale of cheese. They require that cheese be made from pasteurized milk or in lieu of this be held for a period of not less than 60 days before it is used or sold.

Alabama has had a law since 1929 which requires cheese made within the state to be made from pasteurized milk or aged for 60 days before it is sold.

New York City is the only city having a sanitary regulation requiring pasteurization of the milk or holding for a 60 day period. The new regulations became effective December 15, 1944, and briefly are as follows:

1. All kinds of Cheddar and Cheddar type processed cheese must be made from milk or milk products which have been pasteurized, or must be subjected to a heat treatment equivalent to pasteurization. In lieu of pasteurization a minimum of 60 days of aging

after manufacture of these types of cheese is permitted.

2. All soft cheese will be required to be made of pasteurized milk and milk products.

UNIFORM SANITARY REQUIREMENTS NEEDED

A committee representing the Wisconsin Cheesemakers' Association, Wisconsin Milk Producers' Association, the University and the State Department of Agriculture of Wisconsin, and the National Cheese Institute framed acceptable minimum sanitary requirements* for cheese factories and recommended their official adoption by Wisconsin as well as by other states producing cheese.

As Freidel and Yale¹⁶ point out, the cheese industry itself is deeply concerned with proper public health protection for cheese, and feels that all concerned would benefit if all states would adopt uniform regulations. Since cheese is so widely distributed, this would make compliance with state regulations much easier for the industry.

There is a feeling on the part of some health officials that the easiest and best way to obtain uniform sanitary regulations for the 48 states for the manufacture and sale of cheese would be by federal regulations. The establishment of federal standards for interstate shipments of cheese would serve as a model for state regulations and would necessitate a high degree of compliance on the part of cheese manufactures since cheese is so widely distributed.

GENERAL DISCUSSION

It would appear from the data presented that the public health officials have neglected to place the proper sanitary safeguards around cheese. During the past 50 years or so there have been no less than 59 recorded outbreaks of disease with 2,904 cases and 117 deaths

* These requirements may be obtained from Dr. E. W. Gaumnitz, National Cheese Institute, 110 North Franklin St., Chicago, Ill.

in the United States and Canada. Since 1912 when it was first demonstrated that better cheese could be made from pasteurized milk than from raw milk, there have been at least 50 epidemics with 2,715 cases and 117 deaths. Doubtless most of them could have been averted if the knowledge gained at that time had been put into practice. Only recently, due to several large epidemics, have public health officials begun to act and then only in a very limited way. There are today only seven states and Canada that have laws regulating the manufacture and sale of cheese.

All the laws enacted so far have given an alternation between pasteurizing and holding for a definite period during which it is assumed that if any pathogenic bacteria are present, they will die out. The majority have required a 60 day holding period in lieu of pasteurization. This holding period is too short for the Cheddar type hard cheese since many of the pathogens do not die or their toxins are not inactivated in that time. A 90 day holding period would be preferable; a 120 day holding period much better.

It is interesting to note that it is necessary to heat the milk to a higher temperature in the making of Swiss cheese than in Cheddar cheese. However, the milk still gives a phosphatase test. To date there is no record of an epidemic traced to Swiss cheese. So far it has been impossible to make a Swiss cheese from pasteurized milk.

The discussion so far has pertained to Cheddar cheese. In the case of soft cheeses where an aging period of even 60 days might be detrimental to the quality of the cheese, the requirement should be that they be made only from pasteurized milk or cream with no definite holding period stated.

SUMMARY

There have been reported in the United States and Canada since 1883,

59 epidemics with 2,904 cases of disease and 117 deaths. There is every reason to believe that this represents only a part of the disease caused by cheese.

The organisms most commonly associated with cheese-borne infections are members of the *Salmonella* group such as *Salmonella aertrycke*, *schottmülleri*, *typhosus*, *suipestifer*, *typhimurium* and *cholerae suis*; *Staphylococci* such as *Staphylococcus albus* and *aureus*; of the *Brucella* group *Brucella melitensis* but not *abortus*; and *Clostridium botulinum*. There are no reports in the literature of undulant fever due to *Brucella abortus* although cheese doubtless is made from milk containing an abundance of these bacteria. Likewise there are no reports in the literature of septic sore throat or scarlet fever due to streptococci despite the fact that these organisms must be present at times in raw milk made into cheese. *Escherichia coli* is not considered as a cause of cheese poisoning. In Europe several investigators have considered it responsible for the toxin symptoms of illness due to cheese.

Contrary to the opinion of many cheese makers, pasteurized milk makes a consistently higher scoring and better flavored Cheddar cheese than cheese made from raw milk. Cheese made from pasteurized milk can be ripened in about half the time required to ripen cheese made from raw milk, since it can be held at a higher temperature. Experiments made by seeding pathogens into milk and making the milk into cheese show that the pathogens die out more rapidly at the higher temperatures.

There are seven states and Canada that now require cheese to be made from pasteurized milk or cream or to be held in storage for periods ranging from 60 to 120 days in lieu of pasteurization. The 60 day holding period is considered too short a time since pathogens may survive this storage period, especially if the cheese is held at

low temperatures, 40 to 50° F. A 90 day holding period is considered preferable and 120 days still better. All milk used in making soft cheeses should be required to be pasteurized since many soft cheese cannot be held for 60 days without spoilage or deteriorating in quality.

Acknowledgments—In compiling the list of epidemics traced to cheese, the author wishes to thank and acknowledge the assistance given by Dr. R. S. Breed of the New York State Experiment Station, Geneva, N. Y., for submitting all his correspondence and records on cheese epidemics, and W. D. Tiedeman and C. S. Leete of the New York State Health Department, Albany, N. Y., for supplying the list of cheese epidemics which had been compiled in their office over a period of years; and finally to A. W. Fuchs, U. S. Public Health Service, Washington, D. C., for the list of epidemics caused by cheese as reported by various state and city health officers to his office.

Cardiolipin and Purified Lecithin as Reagents in Syphilis Serology*

AD HARRIS AND J. F. MAHONEY, M.D., F.A.P.H.A.

Serologist and Medical Director, Venereal Disease Research Laboratory, U. S. Marine Hospital, U. S. Public Health Service, Staten Island, N. Y.

ATTEMPTING a general statement in regard to the value of a scientific achievement at a time when available information is admittedly inadequate is always dangerous. Cardiolipin as an antigenic substance in tests for syphilis has been employed only in a few laboratories and for a relatively short period. The early impressions are favorable, even enthusiastic. The hope is general that the substance will prove to be capable of effecting major changes in the structure of syphilis serology, that will serve to eliminate at least some of the uncertainties which are inherent in the methods presently employed, and that it will promote a greater degree of uniformity in test results.

The purpose of this report is to review briefly the present application of cardiolipin antigens in the serology of syphilis and to mention some of the avenues through which future advances in this phase of laboratory testing may be anticipated. Cardiolipin antigens referred to in this discussion are mixtures of cardiolipin and purified lecithin with cholesterol in varying proportions.

Cardiolipin and purified lecithin were first described as effective serologic antigen components by Pangborn¹ in

1941. Antigens formed of these substances have since been reported as suitable reagents in both complement-fixation and flocculation tests for syphilis. Test procedures in which cardiolipin antigen has been employed include the Kolmer test as reported by Harris and Portnoy,² the New York State quantitative complement-fixation test reported by Maltaner and Maltaner,³ macro- and microfloculation tests by Brown,^{4,5} and three microfloculation slide tests by Rein and Bossak,⁶ Kline,⁷ and Harris, Rosenberg, and Riedel,⁸ respectively. Also, a preliminary report has been published recently by Kahn⁹ on the use of cardiolipin antigen in the standard Kahn test and in a microfloculation procedure. The opinions and recorded findings contained in these published reports indicate that this reagent can be successfully employed, under routine testing conditions, in either flocculation or complement-fixation technics.

The experience of the writers dates from 1943 at which time the employment of cardiolipin antigens in the Kolmer complement-fixation technic was studied. The antigens were found to possess a minimum capacity to deviate complement in a nonspecific manner in the absence of human sera. This is a desirable characteristic of an antigen selected for complement-fixa-

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1946

tion testing. The studies also confirmed the ability of the newer product to replace the conventional lipoidal material without technical modifications in the test method. Spinal fluid testing was not carried out at that time but later experience indicated the usability of the newer antigen in that field.

In subsequent studies the use of cardiolipin antigen in flocculation methods was canvassed. This work led to the development and publication of a slide flocculation method employing a cardiolipin-lecithin ratio which appeared to be optimal for a microfloculation reaction. Continued use of this method has failed to bring to light major technical deficiencies.

The part that cardiolipin and lecithin play as antigenic components is not clearly defined, nor is the exact physiochemical reaction occurring in a positive serologic test known. Neither cardiolipin nor lecithin alone, nor either of these substances in combination with cholesterol, has been found to be a suitable antigen. However, a point of optimum relationship between cardiolipin and lecithin can be determined so that maximum antigenic activity may be elicited under specified testing conditions. An antigen formula found to be most suitable for one test procedure may be unsatisfactory in another. For this reason, the use of a common antigen in all test procedures would not necessarily produce similarity of test results. The part that a stabilized antigen or antigen source can take in the future standardization of serologic procedures appears to be definite but limited.

Certain similarities exist between cardiolipin and the other lipoidal antigens. They have a common source, which is beef heart. Cardiolipin and lecithin, as such, may be the major reactive components of the usual lipoidal antigens. It is also probable that other substances contained in these lipoidal antigens, but discarded during the prep-

aration of cardiolipin and purified lecithin, may be responsible for some nonspecific reactions.

In the serodiagnosis of syphilis there appear to be two general reasons for nonspecificity. The first is the ability of some diseases and upper respiratory infections to produce a reactive substance in the blood stream serologically similar to the reagin that characterizes syphilis. The second, and possibly there is no real distinction, is the presence of substances in the blood serum other than the reagin of syphilis, which have the capacity of reacting with fractions in the antigen other than the syphilis reacting fraction.

The refinement of the cardiolipin antigen components, and the consequent elimination of many adventitious extractives, may well have the effect of eliminating some of the nonspecific reactions. This appears to be borne out by the early impressions derived from limited practical experience. Not any evidence is available up to the present, however, which indicates that cardiolipin antigens render a test procedure immune to the influence of reacting substances produced by malaria, leprosy, mononucleosis, and virus pneumonia. Emphasis is lent to this point by an article recently submitted for publication by Stout.¹⁰

Sensitivity—The availability of reasonably reproducible antigens such as mixtures of cardiolipin and lecithin forces to the front a general problem which will require clarification before the fullest usefulness of these substances may be obtained. This point concerns the level of reactivity at which a given test method, utilizing cardiolipin antigen, may be adjusted in order best to serve the field of clinical syphilis.

In the past, the individual originator of a test method selected an arbitrary level of reactivity which was considered to be productive of results of greatest usefulness in terms of clinical

syphilis. Antigen preparations for some of the distinctive methods were adjusted to a range of reactivity considered to be optimal. In other methods an antigen preparation which failed to display acceptable reactivity was discarded. With the newer chemical it appears to be possible to establish a relatively precise point of reactivity and to develop cardiolipin-lecithin ratios which will consistently reproduce the desired reacting capacity.

In the event of a uniform level of the above type being found to be feasible and desirable, it would become necessary to establish and to define the level of reactivity which contributes the optimum of sound information. A comprehensive laboratory and clinical study, participated in by leaders in the several professional fields, would appear to be essential to the determination of the level which would be the most informative as regards syphilis.

There are two general considerations which may become important factors in determining the level of reactivity of the test procedure of the future. The first bears upon the use of serology in the post-treatment observation of patients who have received penicillin. The general character of the serology curve, plotted for months or years following treatment, contributes information of real value in evaluating the therapy and in guiding the subsequent management of the patient. The individual test finding is of minimal value except as it contributes to the character of the curve.

Second, a change of equal magnitude is taking place in the interpretation of low reading positive and doubtful reactions in the serum of individuals without history or clinical evidence of syphilis. The previous tendency was to ascribe diagnostic importance to any positive reaction which was confirmed by repeated tests. This significance is being replaced by skepticism arising

from the knowledge that many conditions other than syphilis may be responsible for positive findings, and that many of these reactions are spontaneously reversed following the passage of weeks or a few months.

These shifts in values may well argue against the employment of test procedures which are highly sensitive because of the minimum importance of findings in the threshold zone in either the follow-up observation of treated disease or in the establishment of an abstract diagnosis of syphilis.

The maintenance of test reactivity levels on whatever plane may be finally selected as optimum, would necessitate the use of constantly reproducible reagents. For this reason, methods selected for the isolation, purification, and assay of antigen-source-substances, such as cardiolipin and lecithin, could be retained until reagents prepared by other methods were proved to be of superior quality. Investigative endeavors would, in this way, be divorced from efforts attendant to the routine production of serologic antigen.

This action would not inhibit or retard research into the further identification of antigen components, selection of other antigen sources, or the formulation of new or modified testing procedures. Contrarily, these endeavors could be expedited since definite and reproducible performance standards would be available for preliminary comparison.

Further light may be shed on the mechanisms involved in serologic reactions by investigations directed to the identification of the reactive components of serum and clarification of the interdependencies, both physical and chemical, of cardiolipin, lecithin, and cholesterol as antigen fractions. Some progress in this field has been reported by Neurath¹¹ in a study of the behavior of selected serum fractions with cardiolipin and other lipoidal antigens.

The Pangborn achievement, in making available an antigen composed of more nearly purified substances, at once stimulates speculation as to whether or not the end has been reached in this regard. If the refinement of the fraction of beef heart which is responsible for its antigenic power has reached the cardiolipin stage, there may remain the possibility of carrying the process to a still more simple chemical entity. The inference is fair that the specificity of the reaction produced by the refined product might exceed that of the present compound much in the same manner that the present compound exceeds that of the conventional antigens of lipoidal nature.

Following the same general field of speculation, the development of the structural formula of the product would be helpful as a step in the process of identifying the molecular grouping responsible for the reactivity of the preparation. This in turn would lead to a search elsewhere in nature for similar groupings some of which, conceivably, might be free from the serious handicaps which are inherent in the source of the present product. The ultimate in this general regard would be the reduction of the active principle to a compound capable of reproduction by chemical synthesis. This should have the effect of reducing the antigen factor in blood testing to a precise basis and of abolishing the remaining uncertainties which are associated with the lack of ability to reproduce accurately the antigenic substance in pure chemical form.

The potentialities of cardiolipin appear to offer hope for improvement of existing conditions in another direction. All who have been interested in either the clinical or public health aspects of syphilis have been impressed with the need for laboratory methods which are capable of avoiding the production of conflicting and discrepant

findings. It is realized that many instances of this kind are due to variations in the compositions of antigens, to differences in reactivity levels, and to differences in test mechanics. Discrepancies are, therefore, unavoidable under the present circumstances. The elimination of many instances of the above type could theoretically be accomplished if a simplification of the entire practice of syphilis serology could be effected through the use of cardiolipin antigens.

An initial series of steps in this general direction would seem to be (a) the development of test technics of complement-fixation, tube flocculation and slide flocculation types which would be capable of standardization in all details, (b) the development of cardiolipin-lecithin formulae best suited to the above mentioned test methods, and (c) the manufacture of cardiolipin and lecithin in quantities sufficient to supply all laboratories in which the standard methods were employed. The details connected with the creation of new technical methods would not be insurmountable. An unanswerable question at the moment concerns the ability of cardiolipin in the present state of its development to bear the principal burden of a program of this magnitude. Through the expedient of supplying all antigen material from a central source, together with information as to the formula to be employed in each type of test method, a high degree of uniformity of findings in different laboratories, and in different sections of the country, might be attained.

Present trends are not, however, in this direction. Previously employed test methods are being adapted to individual cardiolipin-lecithin formulae; the level of test reactivity is continuing to be an arbitrary decision on the part of the responsible author, and the number of technical methods, in place of being reduced and standardized, is being in-

creased and further complicated through the necessity of developing an antigen formula for each technical procedure.

The Venereal Disease Research Laboratory early visualized the employment of cardiolipin as a means of promoting greater efficiency in syphilis serology on a national and hemispheric basis. This program would require the authority to manufacture large quantities of the substances and to carry out assays from both chemical and serological standpoints. It would then be essential that the product be dispensed with precise formulae as to optimal combinations of cardiolipin and lecithin to be utilized in defined test procedures, or that completed antigens prepared from these substances be distributed.

Recent information is to the effect that cardiolipin is to be patented and that its future uses will be open to the scrutiny of a non-profit corporation. The effect which this contingency will have upon the application of the substance to the practical problems in syphilis serology which are facing the large laboratories of the country is not clear.

The surrounding of a scientific accomplishment with restrictive legal safeguards must be prompted by a desire to protect the public from unjustified exploitation. What would be construed as justifiable and permissible use of the product in the eyes of the patent holder must await future clarification. It is conceivable that the

program outlined may not meet with the approval of the patent holder or the commercial licensee. There is also the possibility that the patent holders may desire to reserve to themselves the function of guiding the product to its fullest usefulness in the service of humanity as a logical corollary of the desire to safeguard the public. Further progress in the employment of the product, in what may be its broadest field of usefulness, may have to await a fuller definition of policy in those regards.

Importance of a Standard Code for Tabulating Causes of Illness*

SELWYN D. COLLINS, PH.D., F.A.P.H.A.

Division of Public Health Methods, U. S. Public Health Service, Bethesda, Md.

THE *International List of Causes of Death* was adopted more than 50 years ago and has been revised five times, at approximately ten year intervals. Although it has been severely criticised on many occasions, and with respect to particular parts of the classification, its use has continued in many countries over the half-century. In spite of its shortcomings it has had a great part in keeping alive an interest in mortality statistics in many parts of the world which would have abandoned the work without the stimulation of international coöperation and comparison.

Today there is much interest in sickness statistics. Since the beginnings of morbidity statistics for the general population of this country as represented by Sydenstricker's Hagerstown incidence studies,¹ and the prevalence surveys of the Metropolitan Life Insurance Company,² it has been realized that deaths, which represent not more than 1 per cent of all illnesses, are a poor index of morbidity. Today many persons are seeking new ways of securing adequate indexes of the health of communities, states, and nations. What more natural than to turn to morbidity statistics.

There are many organizations that

need a code for tabulating causes of illness. A few years before World War II there was a great movement to code and index causes of hospitalized illness and many requests came to the Public Health Service for a code, an alphabetical index, and other helps to classify properly the diagnosis of the illness, or in more technical terms, the cause of admission to the hospital. Uniform or not uniform, there is a great demand for a diagnosis code for statistical purposes. If such a list is coupled with the *International List of Causes of Death* and can thereby obtain wide acceptance and use, it will meet an extremely urgent need and will encourage the assembling of morbidity statistics. Through the efforts of the Pan American Sanitary Bureau, the Public Health Service-Census Code³ has already been translated into Spanish and the index translated and rearranged for the use of Spanish speaking countries in Central and South America. The volume has not yet been published.

The large increase in hospitalization which has occurred in the past 20 years has been another important reason for developing a morbidity code. Hospitals invariably keep records of the causes of admission and with a suitable code and an alphabetical index many of them would set up annual tabulations of the diseases of persons admitted to the hospital, with a separation of surgical, medical, and obstetrical cases. The

* Presented before a Joint Session of the Epidemiology and Vital Statistics Sections of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946. Published by permission of the Surgeon General.

American Hospital Association now has a Committee on Morbidity Statistics whose chief function is to select or prepare a diagnosis code suitable for tabulating hospital statistics on causes of admission.

It is particularly important to tabulate diagnoses for hospital admissions if they are to be understood and interpreted as an index of the health of the community. Without diagnosis it appears that, in contrast to other health indicators, the period of greatest morbidity is the summer. However, an analysis of the situation indicates that so much surgery is elective as to the particular time of the operation that a great deal of it is put off until the more favorable indications of the summer period, and to the times when school children, school teachers, and others with summer vacations can take care of those chronic conditions that are not emergency cases.

In any special study of morbidity, the investigator is always tempted to prepare a diagnosis code that is tailored to the terminology and needs of his specific study. The method is to make a sample tabulation in terms of the diagnosis names actually used in the particular study. Such a code undoubtedly reflects in the truest light the data reported in this one study. However, it means that tabulation on each study is delayed until a code can be prepared, and furthermore that comparison with other studies can be made in only a limited way. A standard code that fits the data reasonably well avoids making a new code for each study and facilitates more extensive comparison. To prepare even a simple code and make an index of medical and diagnostic terms is such a time-consuming job that analysis proceeds slowly if it has to be redone for every study.

A certain degree of uniformity is an advantage in projects of any kind on which two or more groups are working

with similar objectives. However, if all aspects of the two or more projects are stereotyped, they become so mechanized that intelligence and judgment are no longer useful because everything is cut to fit the machine regardless of whether the final product gives a true picture of the original data.

Uniformity is an advantage only if the code which is adopted is adequate. The mere adoption of an *International List* for morbidity tabulations would benefit no one if that code were not a workable and useful list with enough detail to set forth the real facts of morbidity but not enough to make the code unwieldy and impossible to use. To secure the adoption of an unsuitable code would only set back by at least 10 years international agreement upon a workable morbidity code.

Given a reasonably good code, uniformity encourages comparison and comparison usually leads to a better understanding of any problem. Comparisons that would be useful are:

1. Sickness rates among trainees and others in the armed forces as compared with civilians of similar age and sex
2. Sickness among industrial employees as compared with the general population of similar age and sex
3. Comparison of sickness and mortality with respect to variation with age, sex, size of city, and geographic section

Uniformity is also useful in comparison with the past, but with changing conditions and ever increasing knowledge of the nature and causes of disease, uniformity with the past must be sacrificed in many instances where the continuation of old classifications would be meaningless in the light of present knowledge. Therefore, any system of disease classification should provide for orderly methods of amendment and extension of the code to meet new conditions.

In past revisions of the *International List* and in any contemplated future ones, the cause of death codes cover the

whole list of diseases. The problem is always to make the code short enough to be a usable statistical instrument and yet contain the detail that will make the categories sufficiently specific to be meaningful. Special studies of a particular disease or disease group would need more detail than could be put into an overall statistical list covering all diseases and injuries. It would not be expected, for example, that a general morbidity or mortality code would be detailed enough for special studies of such diseases as cancer, heart diseases, tuberculosis, and syphilis, or of such matters as maternal and infant health. Research projects and special studies cannot afford to use a uniform code unless it meets their particular needs. All one can hope for is that the classifications used in special studies might be collapsible into the rubrics of a uniform code to assist the investigator in comparing his data with such other morbidity and mortality data as are available.

In this connection a distinction should be made between a list for statistical tabulations and a nomenclature. The purposes of a nomenclature are to assist the attending physician to make the proper diagnosis and to give that morbid condition its standard name as accepted in the best medical circles. In such a nomenclature the thousands of morbid states must each be listed separately but not necessarily with a number attached. A statistical list would show important specific categories arranged in groups of similar diseases with the more indefinite and less important conditions grouped into a limited number of miscellaneous categories.

It would be a mistake to overemphasize the importance of a uniform code. A uniform code in itself does not make comparable statistics—it is only the first step toward obtaining some uniformity in the statistics.

Referring first to the international situation, the *International List of Causes of Death* has been uniform for many years in terms of the categories and subcategories of the list, but an examination of the coding manuals of England and the United States indicates a considerable number of differences in the assignment of diagnostic terms to the several rubrics. Some of these discrepancies represent differences in medical terminology in the two countries, but others can be corrected by close coöperation in the assignment of inclusions under the various categories.

The United States began the allocation of deaths to the residence of the patient only in 1939, whereas in England this has been done for many years. Aside from war years, this step would presumably make little difference in data for the country as a whole, but as soon as tabulations are made separately for urban and rural parts of the country, or by size of city, the allocation for residence makes a very important difference in the rates. With the exception of tuberculosis, for which the hospitals are usually located in the country, the cities, and particularly the smaller cities, draw a disproportionately large number of deaths from the surrounding rural areas because most hospitals are located in towns and cities. In the larger cities the nonresident deaths may not change the rate a great deal, but in the counties surrounding the cities they make a very large percentage change because of the smaller populations in the outlying areas.

The Health Section of the League of Nations (now a part of the World Health Organization) realized early the lack of comparability of statistics on the causes of death in the different countries. Edgar Sydenstricker, who organized the epidemiological work of the League, inaugurated a series of inter-country studies to determine the extent to which death rates from specific causes were

comparable in different countries using the *International List of Causes of Death*.

The discussion thus far has centered mostly upon the question of comparability as between two or more jurisdictions such as counties, cities, and nations. There is, however, an entirely different kind of uniformity, namely, a single code for tabulating causes of illness and of death. It is sometimes maintained that since every death is an illness, a code for causes of death is entirely suitable for tabulating causes of illness. However, the importance of different rubrics in terms of frequency of cases is so entirely different for total illnesses and for fatal illnesses that a diagnosis code to cover both items must provide more categories than are needed for either illness or death considered separately. For example, as causes of illness roughly one-third of all cases are due to minor respiratory diseases, and also roughly one-third of all cases with one or more home calls by a physician are minor respiratory diseases. When the illnesses under consideration are limited to those which confined the patient to bed for one or more days, an even larger proportion is due to minor respiratory diseases. On the other hand, few deaths are charged to the minor respiratory diseases, most of the respiratory deaths being due to pneumonia. Thus when tabulating causes of illness this large group of cases needs to be broken into acute respiratory attacks of various types and sites, but in tabulating deaths from respiratory diseases there is need for only a few categories and practically all of the minor respiratory disorders can be put into one miscellaneous group. However, the fact that cases and deaths are so entirely different in their distribution makes it essential that the same code be used for both fatal and non-fatal illnesses if the true picture is to be clearly portrayed.

In the matter of uniformity of illness and death diagnosis codes, there are also problems which indicate that a single statistical list is only a first step toward obtaining uniformity in coding causes of illness and death. Deaths are usually charged to the first important cause in the train of circumstances which resulted in the death of the patient. Thus a death from an old residual effect of poliomyelitis may reasonably be charged to that disease. On the other hand, in tabulating illness it would not be desirable to confuse the incidence of new cases of poliomyelitis with the accumulated residuals of prior cases; such cases would be better tabulated for illness purposes as impairments of specific types that were caused by poliomyelitis. This is particularly true for persons who had poliomyelitis many years ago but are still afflicted with residual impairments.

There are other definite differences that arise from the type of tabulation that is desired. In tabulating the incidence of the communicable diseases and of most other specific diseases one would usually count every case with its onset in a given period, regardless of whether it occurred alone or in conjunction with some other diagnosis. Thus in the acute communicable diseases, if a child had both whooping cough and measles during the same or an overlapping period of illness, one would want to count and tabulate both causes rather than only one as the primary cause of the illness. Thus to make mortality statistics comparable with those of morbidity, it seems necessary to revise some long-standing methods of tabulation and put more emphasis upon contributory causes of death. Inasmuch as this change has been needed and desired for many years, a uniform code may improve mortality statistics as well as its newer counterpart, the statistics of morbidity.

While it is clear that a uniform diagnosis list will not solve all difficulties,

such a list would make for greater stability in the handling of statistics of the causes of illness and death and would be a very important step in an attempt to obtain comparable statistics.

Dr. Breed Is Honored for Studies in Dairy and Cheese Field

Robert S. Breed, Ph.D., Professor of Bacteriology at the New York State Agricultural Experiment Station (Cornell University), Geneva, New York, was guest of honor at a recent banquet of the National Cheese Institute in Chicago.

Dr. A. C. Dahlberg, Professor of Dairy Industry at Cornell University, in speaking of Dr. Breed's contribution to bacteriology and dairy science, pointed out that his service in Geneva went back to 1913 when he began with studies on the relationship of the composition of milk to the yield of cheese and studied the value of paraffining and cold curing of cheese. He had a special interest in the bacteriology of cheese curing and particularly on the microbiology of surface-ripened cheese, such as limburger.

Dr. Dahlberg included among the best known contributions of Dr. Breed

the direct microscopic method of estimating bacteria in milk, also referred to as the "Breed Method" which is used throughout the world. Dr. Breed has also played a leading role in the development of *Standard Methods for the Examination of Dairy Products* as published by the American Public Health Association. Since 1934 and until recent months he has been Chairman of the committee which prepared these methods. Dr. Breed is also editor of *Bergey's Manual of Determinative Bacteriology*, which is a volume like *Standard Methods for the Examination of Dairy Products*, requiring the co-operation of many scientists specializing in various subjects.

Dr. Breed was presented with a traveling bag because of his travel plan following his approaching retirement, including the Microbiological Congress in Copenhagen this July.

Morbidity Statistics Through Periodic Sample Surveys of Households*

THEODORE D. WOOLSEY

*Statistician, National Office of Vital Statistics, U. S. Public Health Service,
Washington, D. C.*

IT is hardly necessary to dwell for long here upon the need for national statistics on sickness and injury, nor upon the obvious inadequacies of mortality statistics as indices of non-fatal as well as fatal illness. It would be difficult to find a worker in the field of public health, or in any related field, for that matter, who is satisfied that present sources of data, applicable to the country as a whole, are sufficient for his requirements. Moreover, there are *no* statistics of morbidity which can be used to estimate the current rates of illness for the entire United States with a measurable degree of reliability. Previous surveys have been used to make national estimates, but these estimates have, perforce, been accepted on faith. They may be good estimates, but we have no way of knowing.

Surveys of households for morbidity statistics have been carried out in various groups of the population in this country from time to time for the last thirty years. Some were of the type in which a sample of households is visited for interviewing periodically for several years. The largest, the National Health Survey of 1935-1936, was a one-time survey which reached more than 2½ million individuals in 83 cities. The

statistical results from these surveys have been widely used, and generalizations have been made from them about broader segments of the population and, in fact, about the entire population. Yet no one of the major surveys was designed according to the criteria of good sampling that are now accepted. Most of the results have also become quite out-of-date, and the question arises as to whether there should not be some new source that could provide current data from which rates of illness in the entire United States could be estimated.

The matter of whether or not an effort should be made to collect at regular intervals statistical information on sickness, the cost and availability of medical care, and related subjects, revolves around such problems as: What sorts of statistics are needed? What possible sources are there that might be exploited and what are the limitations of those sources? Can statistics be collected from any one of those sources with sufficient reliability at a cost that is not prohibitive?

It is proposed to suggest here certain—possibly arbitrary—answers to these questions in order to bring the whole matter into sharper focus and perhaps to stimulate further discussion of the subject.

The answer to the first question is not so arbitrary, and yet it is based upon what one might call well informed hearsay, rather than a comprehensive

* Presented before a Joint Session of the Epidemiology and Vital Statistics Sections of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1935.

survey of the needs of potential consumers of the statistics. This answer is as follows:

The sorts of statistics that are needed are such as will serve to integrate and calibrate the information from the many existing sources without attempting to go intensively into the special questions of health and medical care that are covered by the existing sources. At present we have numerous scattered fragments of knowledge, ranging from detailed knowledge on certain small parts of the population (such as the Eastern Health District of Baltimore, for example), to moderately detailed knowledge on fairly broad segments of the population (such as the group of workers covered by certain industrial sick benefit associations and group insurance plans) and, finally, to a scanty knowledge on the entire population, which is limited to the incompletely reported incidence of certain communicable diseases. In order to integrate these fragments there are needed certain basic statistics, not necessarily in detail as to cause of illness or geographical distribution, but of such a type that they permit statements to be made about the United States as a whole and about certain broad sub-regions of the United States (let us say, ten).

Suppose that a map maker wishes to map a vast, wild region. He has a large number of maps of small parts of the whole region. These maps were made by various previous map makers at different times in the past. They are of varying accuracy and detail. Some overlap, and where they overlap they often disagree. The map maker sets out to survey the entire region anew. He wants to make the greatest possible use of all previously obtained knowledge of the region, much of which is worth while and at least internally consistent information. He first determines the location of certain prominent landmarks with the greatest possible accu-

racy. When he feels sure of these landmarks he sinks a bench-mark in the ground at each spot. These bench-marks do not in themselves give a detailed chart of the area. They are simply reference points. The map maker then studies the older detailed surveys. Those that appear to be consistent with the bench-marks he has established are incorporated in a master map. Others are thrown out and resurveyed. New surveys are planned to fill in the empty parts of the map, starting from the bench-marks as reference points.

That analogy gives an oversimplified representation of our problem. In morbidity statistics the bench-marks would be such points of reference as the monthly rates of incidence of certain well recognized groups of diseases by age, race, and sex in each of the geographic sub-regions; the prevalence of the important chronic diseases for the same categories; the amount of time lost from work as a result of illness by persons in the labor force; the number of visits of or visits to a physician, and so forth. In contrast to the surveyor's bench-marks, these points of reference are constantly changing and, furthermore, their measurement is almost always subject to some bias. Nevertheless, it is statistics of the bench-mark type that are required in order to construct a current quantitative picture of sickness and injury in the United States. Such statistics would not replace or remove the need for the intensive studies in particular areas and the detailed periodic reports on special groups of the population. It would, however, serve to calibrate the information from existing sources. Hence, the term "calibration statistics" might be a reasonably good term to use in describing the type of data we should attempt to get.

What are the possible sources of information of this sort? The possibilities are by no means numerous, if one at-

tempts to list only the basically different ones. One could, for example, attempt to insert two or three questions in the schedule of the decennial census. But that idea has few benefits and many disadvantages. Chief among the latter are the obstacles encountered in adding questions to that already crowded form, the difficulty in giving census enumerators the proper training for the tricky definitions that are involved in morbidity surveys, and, most important of all, the ten year interval between censuses which, even for "calibration statistics," permits far too little detail to be obtained on the seasonal and secular changes in the level of morbidity and far too little opportunity to correct the biases discovered in the results.

Serious consideration was given some years ago to the possibility of collecting morbidity statistics through a registration system dependent upon the coöperation of physicians. Fortunately, the idea seems now to have been abandoned. For not only would the placing of such a burden of paper work on the physicians solely for statistical purposes have encountered vigorous and justified opposition, but the results with the best of coöperation, would have given a seriously incomplete picture. It is an accepted fact that a large part of the illness causing loss of time from work and confinement to bed is not treated by physicians.

Similar objection can be made on the basis of incompleteness, and probably also on the basis of the paper work load it would entail, to a system which called for central reporting of all hospital cases.

Despite the incompleteness of statistics collected from physicians and hospitals, this source of information might offer valuable supporting data to other surveys, and the possibility of collecting facts on the illness of their patients from samples of physicians or hospitals is one that should be studied. But in

order to include as much as possible of that illness not treated by physicians, some other source must be utilized, and that source is obviously the individual who is taken ill, or at least some member of his immediate household.

The most important of the large-scale morbidity surveys undertaken here in the United States have been of this kind. The limitations of these previous household surveys are of two general types. The first and most serious is the limitation which actually applies to any type of morbidity survey. It probably accounts for the fact that there has not been set up, to date, any index of illness in the general population. This limitation results from the elusive character of the concept of illness. It is extremely hard to set up an objective, useful definition of illness in its broadest sense. Even disabling illness, which can be defined in terms of inability to go to work, or go to school, or perform usual household duties, is not easily pinned down in the case of housewives, preschool children, infants, elderly persons no longer working, and persons with jobs who happen to be on vacation. Furthermore, social "tabus" still exist around the discussion of venereal diseases, mental diseases, cancer, and physical deformities. To add to this, there is the basic difficulty that a person may call himself ill when he is in a particular state of health, while another person in the same state of health might consider himself to be "in the pink." Can one even speak about a particular state of health disassociated from the personality in whom it exists? Many people refuse to think of themselves as ill even when the signs and symptoms of disease are obvious; others consider themselves as invalids merely to escape unwanted responsibilities or to gain sympathy and attention. Finally, it has been demonstrated that a person's memory of minor, yet incapacitating, illnesses is often limited to a month or

less, and it has also been demonstrated that interviewers vary considerably in their ability to bring out the fact of illness in the households visited.

Yet, despite these seemingly overwhelming difficulties, household surveys for morbidity have been considered a useful source of quantitative information. The National Health Survey of 1935-1936 might seem to have been pumped dry by the dozens of valuable scientific papers based upon its results, but the end is not yet in sight. This is partly a function of the tremendous demand for this type of statistics, but it also reflects the fact that the persons working with the material feel that they know enough about the lack of objectiveness in the definitions and the biases present so that they can make allowances for them when necessary. How much more they would have known, if only the survey could have been designed to be repeated at intervals!

Before citing an example of the manner in which a household survey of this type is currently demonstrating its value in Great Britain, it is necessary to discuss the second general type of limitation in the large-scale sample studies previously undertaken in this country. This limitation arises from the fact, already mentioned above, that the projects were designed without sufficient consideration for the basic requirements of a good sample design as now recognized.

For a moment, let us review these requirements. First, the design must be such that it gives the maximum reliability per dollar expended. That means that, if you have a certain amount of money that can be spent, your design must minimize the errors of estimate subject to that condition, or, if you start with the condition that the errors of estimate must lie within certain limits 99 out of 100 times, then your design must be such as to minimize

the cost of the sampling operation. Second—and the second requirement follows directly from the first—you must use a method of sampling which permits the measurement of the precision of the estimates. This rules out all purposive methods where personal judgment enters directly into the selection of the units sampled. And, third, the design of the sample must be one that can actually be carried out in practice. Sampling theory and sampling practice must be compatible.

Many people suppose that by simply increasing the size of the sample, so that a considerable part of the population to be studied is included, a good sample is thereby assured. Unfortunately that is not true, and, worse than that, it is definitely uneconomical. In the National Health Survey statistics were obtained on 2,502,391 individuals, or 3.6 per cent of the urban population of the United States in the previous census. This is really a very sizable proportion. But for various, perhaps unavoidable, reasons the cities were chosen purposively, and consequently it is difficult to know how good an estimate of morbidity in the urban population of the United States is provided by the results. Or, stated in another way, the overall rates from the sample give an estimate for the cities surveyed, but we have no way of knowing how valuable the generalizations from the 3.6 per cent are for the other 96.4 per cent.

This general type of limitation of previous large-scale household surveys is avoidable. Surveys planned for the future need not have that drawback. As far as sampling is concerned there is no reason why we should not have "calibration statistics" in morbidity, statistics from which generalizations can be made for the United States, for broad sub-regions of the country, and even for states and large cities if we want to pay enough; and, attached to these generalizations, we can have statements con-

cerning the sampling precision of the estimates.

In Great Britain, periodic surveys of illness among persons over 16 years of age are being made by a government social survey organization on behalf of the ministry of health. They were initiated in October, 1943, and with a few interruptions have provided statistics for every month since that time. Although the Health Index, as it is called, was originally set up to meet the emergency needs of a country in the depths of total war, it was found to be so useful that it was not abandoned at the end of the war. So far as can be ascertained, it is a permanent fixture.

That the British program has proved to be well worth the money spent for it, there is little doubt. New relationships between morbidity and social factors are being discovered for the English population. Some of these are relationships about which we already know quite a good deal for certain communities in the United States, but the Health Index provides statistics from which statements about the population as a whole can be made and which can be used as a basis for action in the medical program of the country. Moreover, the results of each month's investigation are available reasonably promptly, a fact which suggests an advantage that the small-scale repetitive survey has over the larger one-time study. The latter involves such massive tabulations that results are often delayed to the point of seriously diminished usefulness. Perhaps most important of all from the statistician's point of view, the Health Index provides in its original design for its own improvement in that it is repeated. It would be hard to over-emphasize the value of that repetition. It means that one can gain a knowledge of where the biases are, where the definitions are weak, and even of how they can be made more objective. In view of the fact that it is limitations of this sort

which are crucial in determining whether a household survey plan is, or is not worth while, we are led to the somewhat paradoxical conclusion that the best way to decide in this country whether sample surveys of households can yield reliable "calibration statistics" on morbidity is to set up the project the best we know how, let it run for several years, and then have no hesitation about abandoning it, if it gives inconsistent or unreasonable results.

Of course, a series of methodological pilot studies is a prerequisite to any such project. Such studies might indicate at the outset that the idea was not feasible. But if they did not, there would still have to be a probationary period of several years during which the estimates would be checked in every way possible, and every effort would be made to discover the idiosyncrasies of the index and to improve it.

This leads us to the consideration of the third question proposed at the beginning of this paper: Can statistics be collected with sufficient reliability and at a cost that is not prohibitive?

Although it is not the function of the statistician to decide whether a cost is prohibitive or not, the belief of the author of this paper that the cost need not be a major deterring factor is based upon two trends which the statistician does have an opportunity to observe. One is the trend of increasing need for current morbidity statistics to serve the purposes of action programs of an actuarial type. Medical care plans are being set up in several different parts of the country, and there is much debate on the matter of whether the federal government should operate a plan on a national scale. Planning of such programs creates a new demand for basic morbidity statistics, and, as the demand increases, the value of the product in terms of what people are willing to pay for it goes up, as we have had ample opportunity to see in recent months.

The second trend is in the direction of a better product for a given price.

During the war there was rapid improvement in the techniques of sample survey design. In fact, so rapid has the progress been that many of the new theoretical and operating principles have not yet been described in print. These contributions have been of the utmost practicality: How to divide up a sample between different strata in order to get the lowest variance per dollar expended. Whether a method involving a small bias and a small variance may perhaps be better than one with no bias but a larger variance, other things being equal. How to construct a sample in such a way that it will make for administrative efficiency in the field. How to select and train interviewers. How to design interviews for information on subjective matters. How to combine a mail questionnaire survey with a personal interview survey in order to preserve the best features of both. And so forth.

The recent advances in sample survey design have a very direct bearing on the problem of collecting morbidity statistics by means of household interviews, for as a result of them substantial gains can be made in the precision of the estimates per dollar expended.

But it must constantly be borne in mind that the total error of the estimate results from bias as well as from errors of sampling. If we were content to ask such simple, objective questions as "Have you visited a doctor or had a doctor visit you in the past month?" bias would be unimportant, and there would be no question that the cost of obtaining current national and even regional estimates would not hinder us from setting out immediately to collect the statistics. But the demand for "calibration statistics" to serve the needs of public health activities and pro-

grams directed at medical care will not be satisfied so easily. These consumers require at least to know the total amount of illness of various degrees of severity in each important segment of the population. The fact of illness, as we have already said, depends upon who asks the question, how the question is phrased, at what stage of ill health the interviewed person considers himself ill, how good his memory is, and so forth. Hence, beyond a certain limit, no amount of additional money put into increasing the size and representativeness of the sample will yield any increase in the reliability of the results.

CONCLUSION

In conclusion, then, the answer to the third question which was posed at the beginning of this paper must remain indeterminate until such time as methodological pilot studies and a full-scale trial for a period of at least a year can be undertaken. The objective should be "calibration statistics" of the type described. The method should be sample surveys of households. The pilot studies should seek the answers to such questions as: What definitions are to be used? What type of interview will best bring out the information? What type of interviewer should be employed? Over how long a period of time is the informant's memory to be relied on? The trial period should be a full-dress rehearsal with a limited audience—that is, with restricted publication of the statistical results—continuing until all the peculiar characteristics of the material are understood and all the known faults eliminated. At the end of the trial period, an independent committee of experts might be called upon to determine whether the periodic surveys should be continued.

Experience with Vaccination Against Influenza in the Spring of 1947

A Preliminary Report *

THOMAS FRANCIS, JR., M.D., F.A.P.H.A., JONAS E. SALK, M.D., AND J. J. QUILLIGAN, JR., M.D.

Department of Epidemiology and the Virus Laboratory, School of Public Health, University of Michigan, Ann Arbor, Mich.

ON the basis of accumulated experience an outbreak of influenza A was anticipated in the winter of 1946-1947. In an effort to gain further information concerning the efficacy of influenza virus vaccine in the prevention of the disease a study was undertaken at the University of Michigan. The vaccine, with expiration date of February, 1947, was received from Army stores through the Service of Preventive Medicine, Office of the Surgeon General. The material had been prepared in the same manner as that utilized in previous studies¹⁻⁵ which had demonstrated a prophylactic effect. Its red cell agglutinating titer was 5,120 by a pattern test,⁶ the same as that of the standard National Institute of Health control vaccine titrated simultaneously. Immunization of mice demonstrated that its antigenic potency was ten times greater than that required by the National Institute of Health.

VACCINATION PROGRAM

Through the staff of the Student Health Service, under the acting Directorship of Dr. Margaret Bell, vaccination was offered to the student body on

a voluntary basis. The bulk of the vaccination program was carried out between October 22 and November 2, 1946, and an individual record was prepared for each student. Ten thousand, three hundred and twenty-eight students received vaccine and 7,615 did not. A small number of individuals with marked sensitivity to eggs were excluded. No anaphylactic or other allergic reactions were observed and, according to the records of the Health Service, the number of individuals with systemic complaints was less than 1 per cent.

In case of illness practically all students reported to the Student Health Service where they were seen by physicians who had participated in the studies of previous years and were, therefore, well acquainted with the general diagnostic procedures. A record was kept of all individuals reporting with respiratory infections. Cases suspected to be influenza were studied in relation to etiology.

Early in March, 1947, an increased amount of respiratory disease was observed. At the same time there was an increased incidence of illness with nausea, vomiting, and diarrhea in certain groups. However, the other illnesses appeared to be more characteristic of mild influenza. Only patients with significant fever were admitted to the

infirmary where further details of history, throat washings, and blood specimens were obtained. As the outbreak increased in scope some of the febrile illnesses were handled as outpatients and others were visited in their residences. From March 3 to April 4 when spring vacation began, 1,359 cases of illness were recorded, an incidence of 7.6 per cent for the period of the outbreak.

During the same period 183 patients were admitted to the infirmary, and from 94 of these materials for virus studies were obtained.

ANTIBODY RESPONSE TO VACCINATION

Sera were obtained from 96 individuals before vaccination and 10 days or more after vaccination (Table 1). Sixty-eight of them had not been previously vaccinated and showed excellent responses. Twenty-eight of the group were individuals with clear records of vaccination in the Army approximately one year prior to the present inoculation. It is of interest to observe that their titers before vaccination were still quite high after the interval of one year and that their final level of antibody titer after vaccination did not go beyond that of individuals being vaccinated for the first time. The data indicated, then, that the vaccine had effectively stimulated production of antibody to the strains of virus in the vaccine.

VIRUS STUDIES

Great difficulty was encountered in isolating virus from the throat washings

of the patients. Intensive efforts were made to isolate virus in embryonated eggs from the throat washings of 28 patients. Thirteen specimens were investigated by repeated allantoic passages with only negative results. Eight specimens were examined by amniotic inoculation of 10-11 day embryos; all were negative. Ten specimens were inoculated into the amniotic sac of 13-15 day embryos. Six apparently positive results were obtained under these latter conditions. They have not been adapted to allantoic passage, however, and red cell agglutination was demonstrated only with human and guinea pig erythrocytes but not with those of chickens.

Three specimens of throat washings induced characteristic responses in ferrets and were passed in series in that animal. Thence, these strains were adapted to mice and from mice to eggs by the allantoic route. Three additional specimens stimulated antibodies in ferrets. Two were entirely negative. Adaptation of virus to mice after ferret passage was slow and three to five serial passages in the latter species were required before pulmonary lesions were clearly observed. The difficulty in establishing virus in eggs is quite different from our previous experience with influenza A.

Serological evidence indicates that the virus is a strain of influenza virus, Type A. The majority of patients recovering from the illness showed increased antibody titers to the PR8 strain and to a newly isolated strain

(Rhodes). The mean acute and convalescent titers in unvaccinated individuals were 76 and 230, respectively, for PR8; 27 and 120, respectively, for Rhodes (Table 2). It is of interest to point out that the mean titers in the acute stage of illness were 76 in the unvaccinated and 499 in the vaccinated when tested against PR8. This latter figure is essentially the same as that of the group tested 2 weeks after vaccination, indicating that there had been no sharp loss of antibody level in the interval since vaccination. In sharp contrast, however, there was no significant difference in the low titers of vaccinated and unvaccinated individuals in the acute stage of illness when tested with the new strain. It was of further interest that when comparing the titers of sera from individuals before and after vaccination in 1946, the majority showed a good rise to PR8 and Weiss strains which were included in the vac-

cine but little increase in antibody to the new strain (Table 3). Further tests with acute and convalescent sera from patients suffering from influenza A in 1943 showed a sharp increase in titer to the PR8 strain with little or slight antibody production to the current new strain. These results clearly indicate that the strain prevalent in this outbreak has a sharp antigenic difference from those commonly encountered in previous years and from those incorporated in the vaccine.

INCIDENCE OF ILLNESS IN VACCINATED AND UNVACCINATED INDIVIDUALS

The amount of respiratory disease that occurred in vaccinated and unvaccinated persons during the period of the outbreak is shown in Table 4. That the major proportion of cases was due to the influenza virus was indicated by positive serological evidence of infection in approximately 80 per cent of the

† Based on the assumption that the populations under study remained unchanged in the interval between vaccination and the outbreak. Actually a slight but comparable reduction occurred in both vaccinated and unvaccinated groups.

94 hospitalized patients. It is clearly evident from the data that the incidence of disease was no different in vaccinated and unvaccinated individuals.

INTERPRETATION

In view of the laboratory studies indicating that the antibody titer for the new strain was essentially the same in vaccinated and unvaccinated persons, it is not surprising that the amount of illness was practically the same. Since the antibody titers to the strains of virus in the vaccine were high in the vaccinated individuals who became ill, it seems unlikely that the ineffectiveness of the vaccine in the prevention of influenza in this instance was related to the interval of time between vaccination and the appearance of the outbreak.

All the data point to the probability that the antigenic deviation of the virus encountered is the responsible factor. This is further supported by the evidence obtained with ferret sera. The sera of ferrets inoculated with the new strains ordinarily developed high titers to recent (1947) strains isolated here and also to some furnished by Dr. J. E. Smadel of the Army Medical School, but had decidedly less response to the PR8 and Weiss strains of Type A. Convalescent sera from ferrets inoculated with these two latter strains also exhibited high titers to them with little or low titers to the new strains. More-

over, some presumably normal ferret sera were found to neutralize the new strains in eggs and mice; the interpretation of this has not been fully established.

Thus, the absence of effect of vaccination during the outbreak of influenza in the spring of 1947 appears to be due to the lack of sufficient antigenic crossing between the strains of virus in the vaccine and the prevalent strain responsible for the epidemic. The implications of this and other observations will be discussed in a more detailed report to be published.

Proposed Statistical Classification of Diseases, Injuries, and Causes of Death*

Prepared by the United States Subcommittee

EDWARD S. ROGERS, M.D., F.A.P.H.A.†

*Professor of Public Health and Medical Administration and Dean, School of
Public Health, University of California, Berkeley, Calif.*

THE Fifth International Conference for the Revision of the *International List of Causes of Death*, like the preceding conferences, was convened by the Government of France. It was held at Paris in October, 1938. Apart from bringing the previously existing lists up to date in accordance with the progress of science, particularly in the chapter on infective and parasitic diseases, changes in the chapters on puerperal conditions and on accidents and the addition of a list of the causes of stillbirth, the Conference made few changes in the content, number, and even numbering of the items.

The Conference recognized the growing necessity for a corresponding classification of diseases for morbidity statistics to meet the needs of widely differing organizations, such as health insurance groups, hospitals, the military services, and health administrations, and recommended continued studies in this direction.

* Presented before a Joint Session of the Epidemiology and Vital Statistics Sections of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946

† This report is presented by Dr Rogers in the capacity of Chairman of the Subcommittee on the Sixth Revision of the International List of Causes of Death of the Committee on Research and Standards of the American Public Health Association.

The Conference further recommended that the United States Government continue its studies of the statistical treatment of joint causes of death.

In compliance with this recommendation, in 1945 the Secretary of State of the United States appointed the present United States Committee on Joint Causes of Death and requested the Governments of Canada and Great Britain to designate official representatives as members or advisers. Dr. Y. Biraud, Head of the Epidemiological Intelligence Service, Health Section of the League of Nations, also accepted membership on the committee. Two meetings of the full committee have been held in Washington, and a third meeting is scheduled for early next year.

The committee has recognized that its charge to continue the studies of joint cause classification was inseparable from the question of the basic structure of a revised list that could serve as a code for the classification both of causes of death and of morbidity. A special working subcommittee (see page 1071) was appointed, to the members of which belongs the principal credit for the painstaking study and suggestions that are largely responsible for this proposed

classification of diseases, injuries, and causes of death which can be used for both morbidity and mortality statistics.* This proposed classification has been adopted by the U. S. Committee for further study and possible presentation to the International Conference for its consideration when it meets in 1948.

The classification consists of three parts: Part I is a list of disease categories for the tabulation of morbidity and mortality statistics. It is not suitable for actual coding, since it does not contain either a tabular list of inclusion terms, or an alphabetical index. Part II contains the tabular list of inclusion terms for each disease category. It makes preliminary trials of the code possible. Part III, containing an alphabetical index of diagnostic terms which may appear in medical records and reports, will not be completed until the list is in a definitive form and may not be available until late in 1947 or early 1948.

PRINCIPLES UNDERLYING THE PROPOSED CLASSIFICATION

In considering the general principles underlying the proposed morbidity and mortality list, the aim has been to produce a classification for statistical purposes and not a nomenclature of diseases and injuries.

A classification of diseases and injuries designed for both morbidity and mortality statistics must necessarily include more categories than a mortality classification alone. The experience of the committee of the Medical Research Council and that of the U. S. Public Health Service and the U. S. Bureau of the Census in the development of statistical classifications has

shown clearly, however, that the general structure of the *International List* was a useful frame around which a morbidity classification could be evolved. Likewise, the *Standard Morbidity Code* of the Dominion Council of Health of Canada has indicated that the general structure of the *International List* can be followed for morbidity classification. The basic framework of the *International List*, furthermore, has withstood the test of well over a half-century of use in countries throughout the world. The very fact that the general arrangement has not been changed substantially in that time suggests that it would be difficult to improve upon it as a working basis for disease statistics.

Accordingly, the main subdivisions of the proposed classification are, for the most part, the same as the main chapters of the *International List*. Despite this effort at uniformity, a comparison between the frequency of a disease as a cause of death now and twenty years ago is likely to be difficult of interpretation, through no fault of the code, however. Such a comparison would be greatly influenced by the variations in the use of a particular term to describe a disease by observers differing in their education and medical outlook.

NATURE OF PROPOSED CLASSIFICATION

The philosophy underlying the proposed classification has of necessity been somewhat eclectic since no single basis or axis of classification is practicable. The proposed classification deals, in sequence, with diseases by cause, with respect to the well defined infective agents, then with neoplasms, general diseases on a somewhat physiologic basis, a long series of diseases according to their principal anatomic site of occurrence, and, finally, with injuries.

An important new form of grouping in certain conditions has been adopted to characterize the late effects or residual

* Parts I and II, prepared by the Subcommittee on Classification of Diseases, Injuries, and Causes of Death of the U. S. Committee on the Joint Causes of Death, were published in April, 1946, and August, 1946, respectively and are available in limited number through the Federal Security Agency, U. S. Public Health Service, Washington, D. C.

- Specified as a late effect or sequela, or present one year or more after onset

disorders of function which may remain but which are quite distinct from the original disease or injury. Examples in which this method has been adopted are the late effects of poliomyelitis, of rickets, and of injuries (Figure 1).

The proposed classification consists primarily of a reasonably short list of 99 groups and a more detailed list of 742 or 784 categories depending on whether injuries are classified according to the external cause of the injury or to its nature. A decimal system of numbering has been adopted in which the detailed categories are designated by a 3-digit number. The first and second digits of the 3-digit number designate important or summary groups, and the third digit subdivides these into more definite categories that frequently represent specific diseases.

The decimal system represents a departure from the combined number and letter subdivisions that have been used heretofore in the *International List of Causes of Death*. Although the number of definite categories in the proposed classification is substantially larger than in the present *International List*, it is expected that any resultant disadvantage will be more than offset by the greater flexibility and utility of the numbering system suggested.

The proposed classification provides an abridged list of 99 significant groupings which should prove much better adapted to statistical purposes than either of the abridged lists of the current *International List*. One important

advantage of the proposed list lies in the fact that the code for the abridged list constitutes the basic structure for the code for the long list of approximately 750 inclusions as well. This is not the case in the current *International List*, so that either separate punching or code correlation of some sort is required whenever comparison between the long list and an abridgement is made.

Not every condition has received a particular rubric or number, but there is a place or number to which every condition can be referred. This has been achieved by the method of selective grouping. For example, a broad group of conditions such as the psychoses is given a 2-digit number and is then divided into eight categories corresponding to fairly well defined types of psychoses, and, lastly, there is a ninth or residual category to which the psychoses which are not already covered or which are ill-defined can be allocated (Figure 2).

The determination of what conditions should be specified as definite categories has been based on their frequency, importance, and clarity of characterization. The question as to how satisfactory these subdivisions are will be tested under the principle that the number of conditions allocated to residual or ill-defined categories must not be unduly large. Fortunately the proposed classification permits the introduction of new categories without upsetting the basic numbering of other categories. The clerical and mechanical economy of such

V. MENTAL DISEASES, PSYCHONEUROSES, AND PERSONALITY DISORDERS

31 *Psychoses*

Numbers 310-318 exclude general paralysis of insane (025) and puerperal psychosis (648)

- 310 Dementia praecox (schizophrenia)
- 311 Manic-depressive psychosis
- 312 Involutional psychosis
- 313 Paranoia and paranoid conditions
- 314 Senile psychosis
- 315 Psychosis with cerebral arteriosclerosis
- 316 Alcoholic psychosis
- 317 Toxic or infective psychosis

This title is not to be used for primary death classification if the antecedent condition is known. It is not to be used for primary morbidity classification if the antecedent condition is present.

- 318 Other and unspecified psychoses

a possibility is of particular importance to statistical organizations which handle large volumes of records.

The numbering system has been designed purposely as a closed system; that is, the third digit categories under each 2-digit group begin with "0" and continue consecutively for the number of categories in that group. No vacant numbers are left except at the end of the 3-digit subdivisions. Thus the detailed classification represented by the code must remain uniform to the third digit.

Many of the 3-digit categories are further divided into more detailed sub-categories, often on a different axis of classification (Figure 3). The numbers for these sub-categories represent decimal subdivisions of the 3-digit code. These sub-categories may be considered optional. Whenever more detailed ter-

minology than that provided in the classification is required, the fourth digit place should be used. If such fourth digit sub-classes are created it is recommended by the committee that letters instead of numbers be used. This will serve to distinguish such particularized inclusions from the items that comprise the standard list in international use.

COMPARISON WITH CURRENT INTERNATIONAL LIST

In the proposed scheme, there are 17 main sections as compared with 18 in the *International List*. There are 99 2-digit groups in the proposed list and approximately 750 3 digit categories. These may be compared with the abridged *International Lists* of 44 or 87 titles and with 200 categories and approximately 450 sub-groups of the complete *International List*.

FIGURE 4

Comparison of Main Sections, International List of Causes of Death (5th Revision) and Proposed Statistical Classification of Diseases, Injuries and Causes of Death

Section	International List	Proposed Statistical Classification
I	Infectious and Parasitic Diseases	Infective and Parasitic Diseases
II	Cancer and Other Tumors	Neoplasms
III	Rheumatism, Diseases of Nutrition and of the Endocrine Glands, Other General Diseases, and Avitaminoses	Allergic, Endocrine, Metabolic, Nutritional and Other General Diseases
IV	Diseases of the Blood and Blood-forming Organs	Same
V	Chronic Poisoning and Intoxication	Mental Diseases, Psychoneuroses, and Personality Disorders
VI	Diseases of the Nervous System and Sense Organs	Same
VII	Diseases of the Circulatory System	Same
VIII	Diseases of the Respiratory System	Same
IX	Diseases of the Digestive System	Same
X	Diseases of the Genito-urinary System	Same
XI	Diseases of Pregnancy, Childbirth, and the Puerperium	Deliveries and Complications of Pregnancy, Childbirth and the Puerperium
XII	Diseases of the Skin and Cellular Tissue	Same
XIII	Diseases of the Bones and Organs of Movement	Same
XIV	Congenital Malformations	Same
XV	Diseases Peculiar to the First Year of Life	Diseases Peculiar to the First Month of Life
XVI	Senility	Senility and Ill-defined Conditions
XVII	Violent or Accidental Deaths	Accidents and Violence
		N = Classification by Nature of Injury or Poisoning
		E = Classification by External Cause

Although for the purpose of maintaining continuity of mortality statistics the important titles of the current *International List* have been retained, it did not seem essential that there should be strict comparability for each subdivision. However, in so far as is practicable the order of the diseases follows that of the *International List* with the addition of diseases, usually items concerned with morbidity rather than mortality, that were not given a specific place before.

Comparison of the main section headings of the two lists shows the following proposed changes:

Section V, "Chronic Poisoning and

Intoxication," of the *International List* has been eliminated and the conditions included in the three groups of that section are assigned elsewhere in the proposed list, principally under the revised section on "Accidents and Violence." In the place of the former Section V, a new section on "Mental Diseases, Psychoses, and Personality Disorders," has been established.

The heading of Section XI has been reworded to include normal pregnancy and delivery.

Section XVI, "Senility," and Section XVIII, "Ill-defined and Unknown Causes," have been combined in a single section, also Section XVI, under

the heading of "Senility and Ill-defined Conditions." Section XVIII has not been continued.

For Section XVII, "Accidents and Violence," the committee has adopted a dual system of classification. This section has always been one of the most troublesome in the *International List*. The difficulties have arisen over the two axes of classification that are of particular statistical interest; namely, circumstances of accident or means of injury, and nature of injury. Each of these represents an important aspect of injuries although in a particular analysis one axis may be more valuable than another. As a consequence this section has always represented compromises which frequently were quite unsatisfactory because they answered neither one problem nor the other and, furthermore, the terms often were not mutually exclusive.

In developing this proposed code for both morbidity and mortality statistics, the problem of Section XVII has been attacked boldly and a dual classification suggested. One classification is on the basis of the nature of the injury, the other on the means of injury or the so-called, "external cause." In order to distinguish which classification is used the letter "N" has been placed before the code numbers of the first arrangement and the letter "E" placed before the second. Both classifications should be considered as integral parts of the "Proposed Statistical Classification of Diseases, Injuries and Causes of Death."

Too much importance should not be attached to the broad section headings of the proposed code as these 17 group

titles are not included in the numbering scheme of the code itself. Although they serve as useful guides to an orderly grouping of the inclusions of the list, the committee considers that the similar broad headings of the current *International List* do not represent a collection of disease conditions that is sufficiently consistent with any single axis of classification to be either statistically stable or functionally useful. Every revision in the past has shifted diseases from one section to another in such a fashion that the groups have seldom remained comparable over long periods of years. The section headings have been retained, however, as they show the general structure of the proposed classification and its similarity to that of the *International List*.

The proposed classification is ready for preliminary and unofficial study and trial by interested agencies in this country and elsewhere. Another meeting of the committee will be held early in 1947, at which time consideration will be given to all comments and suggestions concerning the structure of the proposed list and its usefulness as a single code for both mortality and morbidity statistics.

As chairman of the Subcommittee on the Sixth Revision of the International List of Cause of Death of the Committee on Research and Standards of the American Public Health Association, I particularly wish to invite your interest and careful review of this proposed classification. The Association has not only a duty to discharge, but also a strong tradition of national and international leadership to maintain in connection with this fundamental activity.

Bacteriological Procedures in Sanitary Air Analysis*

SPECIFIC BACTERIOLOGIC PROCEDURE

A JOINT meeting of the Subcommittee on Bacteriological Procedures with the Committee on Air Sterilization and Odor Control of the American Society of Heating and Ventilating Engineers was called on June 4, 1945, in New York City to consider routine procedure for a sanitary survey of ventilation in accordance with six suggestions offered by Professor Winslow for establishing sanitary ventilation on a design basis; these procedures, adopted at a previous meeting on January 22, 1945, follow:

1. Obtain agreement on a method of determining the number of streptococci present in air.
2. Establish a standard of performance and state the permissible number of streptococci per cubic foot of acceptably clean air.
3. Establish the concentration of streptococci which may be found in various types of occupied rooms under average and under extreme conditions such as obtained during a cold epidemic.
4. Establish the number of air changes required to reduce the various degrees of pollution to an accepted standard by means of outside or purified, recirculated air.
5. Establish a basis on which to determine the cost to obtain the desired standard condition by the use of ultra-violet light or a combination of ultra-violet light and air change.
6. Determine the cost of obtaining standard conditions by use of aerosols sprayed into the

air for comparison with cost to produce the same standard condition by means of proper air change and ultra-violet radiation.

Bacteriologic Procedure in the Evaluation of Methods of Control of Airborne Infection (Wells, Winslow, and Robertson, 1946) were thoroughly discussed and it was agreed that specific procedures would be submitted to the subcommittee for approval. The following resolutions were adopted:

VOTED: THAT the ASHVE T.A.C. on Air Sterilization and Odor Control recommends to the Committee on Research that funds be allocated to enable a Sanitary Survey in accordance with the "Bacteriologic Procedures in Sanitary Air Analysis" to be undertaken under the auspices of the Committee, and THAT the Wells centrifuge be used as the collecting device for at least the first survey that is made.

VOTED: THAT this Joint Committee recommends to the ASHVE Committee on Research the steps suggested by Dr. Winslow as a basis for procedure for carrying out a Sanitary Air Survey.

At a meeting in New York on September 22, 1945, it was agreed that for the time being the specific bacteriologic procedure now being applied in a comprehensive sanitary survey of ventilation in schools by the New York State Department of Health (as described below) would be adopted tentatively.

It was further agreed that sampling devices should be compared.

First, samplers for sanitary air analysis should be capable of collecting nuclei from droplets coughed or sneezed into the atmosphere—proved for the air centrifuge (Wells and Riley, 1937,

* Report of the Subcommittee on Bacteriological Procedures of the Special Committee on Standard Methods for the Examination of Air, administered by the Committee on Ventilation and Atmospheric Pollution. Published subcommittee reports, *Year Books*, 1936-1937, 1937-1938, 1938-1939, 1939-1940, 1940-1941, 1941-1942.

and Phelps and Buchbinder, 1941), and for the slit sampler (Bourdillon, Lidwell, and Thomas, 1941)—by removal from 10 cubic feet of air of more than 100 times as many nuclei of atomized cultures as deposit on a Petri plate in 10 minutes. The test is easily performed by atomizing into the air of a room with a Fragrantmist* vaporizer a diluted culture of *Escherichia coli* and testing the air with sampling instruments, simultaneously with Petri plate exposure.

Second, it was agreed that suggested media should be compared with those now being used by the New York State Department of Health for the culture of significant organisms.

Third, the practicability of methods in field investigations as well as in laboratory studies should be compared.

TENTATIVE PROCEDURES OF SANITARY AIR ANALYSIS USED BY THE NEW YORK STATE DEPARTMENT OF HEALTH

Apparatus

The Wells Air Centrifuge adjusted to deliver one cubic foot of air per minute shall be used to collect samples in both liquid and solid media.

Special Pyrex centrifuge tubes for use with the Wells centrifuge shall be used to collect all samples taken in the centrifuge.

Petri plates 10 cm. in diameter with glass tops shall be used.

Media

(F₁) Tryptose agar † (for use in Petri plates and centrifuge tubes)

Agar	2.0	per cent
Beef extract (Bacto)	0.3	" "
Tryptose	0.5	" "
Dextrose	0.1	" "
Water to make	100	" "

* Manufactured by Walton Laboratories, Inc., Irvington, N. J.

† This agar is similar to that used for examination of milk (A.P.H.A. and A.O.A.C., 1941) except that skim milk is not added, and the agar concentration is increased to provide a stiffer medium for use in the centrifuge tubes.

(F ₂) Air enrichment broth (Difco formula)	
Tryptose	1.0 per cent
Proteose-peptone No. 3	0.7 " "
Yeast extract	0.3 " "
Lactose	0.5 " "
Disodium phosphate	0.25 " "
Brom thymol blue	3 ml./lit. of 0.4 per cent sol.
Gentian violet	1:4,000,000

(F₂) Gentian violet blood agar

(F₂) containing 2.0 per cent agar, 2 p.p.m. gentian violet and blood (rabbit or horse) 50 gr./900 ml.

(F₄) Beef-infusion broth (for streptococci, Wadsworth, 1939)

Beef	450 grams
Water	1000 "
Peptone (Difco Proteose)	20 "
Dextrose	0.02 per cent

Sampling

The samples shall be collected in rooms which have been in normal use for not less than 1 hour before sampling. Temperature, humidity, number of persons and their activity shall be recorded, together with the previous attendance during the 20 minutes directly preceding the test. The number of windows open and the number, position, and apparent operation of any germicidal units, such as ultra-violet lights, shall also be recorded.

Five Petri plates, previously poured, containing tryptose agar (F₁) shall be exposed simultaneously for 15 minutes. One of these plates shall be placed approximately 2 feet from each corner and one in the center of the room; all shall be supported 30 inches above the floor. During this 15 minute period, one 5 minute centrifuge sample shall be taken in 20 ml. of agar medium (F₁) poured from a thermos bottle and cooled to about 55 °C. before placing in the centrifuge.

During the same 15 minute period another 5 minute centrifuge sample shall be taken in 20 ml. of air enrichment broth (F₂).

Incubation and counting

The exposed plates and agar tubes

shall be incubated for 18-24 hours at 37° C. They shall be counted with a Quebec colony counter, or other suitable device. If a centrifuge tube contains more than 300 colonies, a fractional part may be counted, but this fraction must include an entire lengthwise section of the tube.

The exposed broth in the centrifuge tube shall be divided into five equal portions, each representing the bacteria contained in one cubic foot of air. These shall be incubated for 24 hours at 37° C. at which time any tubes which have a yellow color shall be streaked on blood agar (F_3). All tubes which show no yellow shall be reincubated for another 24 hours and any yellow tubes appearing at that time shall also be streaked on blood agar, containing 1:500,000 gentian violet. The blood agar plates shall be incubated for 48 hours and observed for *alpha* or *beta* hemolytic colonies. Any such colonies shall be fished to streptococcus broth (F_4), incubated for 24 hours at 37° and examined, using the Gram stain.

To obtain the settling count per square foot per minute, the median of the counts of the five Petri plates shall be taken.

The volume count per cubic foot equals the centrifuge count divided by 5.

The broth shall be reported as number of tubes positive and number negative.

Petri plates
Tripod Petri plate holders—30 inches high
Pint thermos bottles
Pouring stoppers for thermos bottles
100 x 15 test tubes (sterile)
37° incubator
Quebec colony counter
Hand tally
Sterile 10 ml. pipettes graduated in 1/10 ml.
Loop
Needle

Sanitary Ventilation Test

4 Fragrantmist Atomizers
3 25 ft. leads
1 tube colony counter
(in addition to equipment listed above)

Yellow Fever Vaccination, Simple or Associated with Vaccination Against Smallpox, of the Populations of French West Africa by the Method of the Pasteur Institute of Dakar

MÉDECIN-GÉNÉRAL MAURICE PELTIER

Dakar, French West Africa

THE absence of yellow fever in the French territories of West Africa is now almost entirely the result of mass vaccinations of both the European and native population. Since 1941, about 15 million vaccinations were performed—a figure which corresponds almost to the total populations under census in those territories.

A control campaign of such magnitude has only been possible on account of the simplicity of the method of preparation and application of the vaccine used. The method was developed at the Pasteur Institute of Dakar by Messrs. M. Peltier, C. Durieux, H. Jonchere, and E. Arquie. The difficulties of war times rendered impossible any widespread publication of these important works, and it seems appropriate now to draw attention to them.

The first experiments with this mode of vaccination date from 1939 and the papers relating to them have been published in the French scientific journals.^{1,2} Vaccination against yellow fever, however, had been practiced in the French territories of Western Africa since 1934, the vehicle being the

neurotropic virus of the mouse, first by the procedure of Sellards-Laigret (vaccine phosphate in three injections), and later by the Laigret process (vaccine phosphate mixed with egg yolk). This mode of vaccination proved its efficacy, but the practical difficulties involved were an obstacle to its large diffusion.

Convinced that only the vaccination of the native masses could remove the danger of propagation of yellow fever, the Pasteur Institute of Dakar sought a simpler method which could be more easily given wide application. Its primary object was to replace subcutaneous inoculation, which requires a considerable number of syringes and needles rigorously sterilized, with inoculation by the simple application of virus to cutaneous scarifications.

The passage of the pantropic virus to the organism through contact with the shaven or scarified skin had been obtained previously in the *Macacus rhesus* in 1928 by H. Beeuwkes³ and also by E. Marchoux.⁴

The Pasteur Institute of Dakar experimented with the process of penetration of the neurotropic virus of the

mouse through scarification. The first experiments were made in November, 1938, on young *Macacus rhesus* monkeys. The virus utilized was the neurotropic virus of the French strain at the 238th passage.

One drop of a glycerine suspension of the powder of the dried virulent mouse brain was deposited upon scarifications made on the abdomen. The virus was detected in the blood of the animals from the 4th to the 8th days. No febrile reaction was observed. The test of sero-protection made 30 days after the experiment proved strongly positive.

The same procedure was then repeated on man and the results were identical. For the first six subjects who were thus inoculated (all volunteers), the virus was found in the circulation around the 4th, 5th, or 6th day after vaccination. Only one showed a slight reaction of fever during the 7th day. Subsequent tests in all the series gave positive sero-protection.

Thus the idea occurred of associating the yellow fever virus with the Jennerian virus in order to achieve with only one operation a combined vaccination against yellow fever and smallpox.

The two vaccine viruses were mixed at the moment of application and suspended in glycerine. The combined vaccinations were performed first on the *Macacus rhesus* and then on man. On the latter, the operations were performed in the beginning under environmental conditions that facilitated surveillance, in the Navy at Dakar and in the village schools; and subsequently, attention was gradually directed to subjects of both sexes and all ages, including more than 50 children from six months to one year old. A test for sero-protection made before the experiment made it possible to retain only those subjects who presented a negative test. No severe reaction was observed,

except in some cases a slight feverish condition.

The sero-protection test performed a month later showed that immunity against yellow fever had been acquired in 90 per cent of the cases.

On the other hand, all the subjects that were receptive to the smallpox vaccine virus presented vesicles in the same proportion as those observed when the same vaccine was used alone, that is, in 16 per cent of subjects already vaccinated several times against smallpox and 81 per cent of subjects supposedly never before to have been vaccinated. The antivariolic vaccine used in this experiment, which was performed on 741 persons, was prepared from a culture made by H. Plotz.

These first experiments led to the following definite conclusions:

1. The neurotropic yellow fever virus applied to cutaneous scarifications penetrates into the organism and produces immunity against yellow fever.

2. The association of the neurotropic antiamarillic virus with the antivariolic vaccine makes it possible to obtain protection against both yellow fever and smallpox.

3. The two immunities establish themselves simultaneously and independently of each other in the same manner as they would under two separate vaccinations.

However, before making current practice of this method of vaccination in the African bush, the Pasteur Institute of Dakar decided to make sure once more that the neurotropic virus present in the peripheral circulation a few days after vaccination could not, through passage by the *Stegomyia*, regain its pantropic properties and bring about outbreaks of yellow fever in the neighborhood of the vaccinated subjects.

Already a certain number of authors had observed that the neurotropic virus, after a great number of mouse passages, does not pass easily to the mosquito, and, whenever it happens to pass, there

is no evidence that the strain returns to its original viscerotropic types.⁵⁻⁹

The Pasteur Institute thought it advisable, nevertheless, to pursue the experiments to a conclusion by working under optimum conditions, *i.e.*, by operating in Dakar during the season which is the most favorable to the development of the natural infection of that mosquito—the hot and humid part of the year which is the yellow fever season in Senegal.

The results of this last experiment were published in March, 1939.¹⁰ Even under those optimum conditions, it has been confirmed beyond any doubt that:

1. It is almost impossible for the neurotropic virus to develop or even to maintain itself in the *Stegomyia*.

2. When, by any chance, the neurotropic virus is so maintained the *Stegomyia* is unable to transmit it by biting, even to the most sensitive of the animals—the *Macacus rhesus*—and much less to man.

In view of the above results, a vaccination campaign comprising 100,000 inhabitants of Senegal was authorized and undertaken during the months of May, June, and July, 1939. Those vaccinations were performed in a region where no case of yellow fever had been noticed for a long time, with a view to observing more easily any accidents that might occur both among the vaccinated individuals and their neighbors. The vaccines were very well tolerated. The neighboring population was very carefully observed, and no manifestation of yellow fever, not even the slightest, has been noticed despite the prevalent breeding of the *Stegomyia*.

The results of the vaccination against smallpox were controlled 8 days after performance. The tests for sero-protection, carried out only on subjects who had had negative tests before the experiment, followed 6 weeks after vaccination. Among the 1,630 sera thus tested, 1,559 were found positive, or 95.6 per cent.

Other mixed vaccination campaigns embodying scores of thousands of inhabitants of the Ivory Coast and the Sudan were carried out in 1940 and 1941 under the direction of the Pasteur Institute of Dakar with the coöperation of the personnel of the Assistance Medical Indigene (Office of Medical Assistance to the Natives). The results obtained were as good as those secured in the first experiments.¹¹⁻¹²

The facility and safety of the new method having thus been established, and in view of the numerous dangers confronting the troops stationed in French West Africa, the public authorities decided in the latter part of 1941 to make vaccination against yellow fever by the method of the Pasteur Institute of Dakar compulsory for all the military and civilian populations of those regions. It was further decided that the yellow fever vaccination should be associated with the vaccination against smallpox each time the administration of the latter was deemed necessary.

The Services d'Hygiene et de Prophylaxie (Bureau of Public Health and Prophylaxis) were already organized to administer vaccinations to all the native population within a period of 4 years. A 4 year plan of mixed vaccinations was then started and carried almost to completion, in spite of all the difficulties inherent in the war and post-war periods of 1942-1946. On January 1, 1946, the total of simple and mixed vaccinations against yellow fever reached the figure 14,330,735 for a total population of about 16 million inhabitants.

Table 1 gives the details for each annual operation.

These results were submitted to the Quarantine Commission of UNRRA by Surgeon General Peltier. It was agreed that an experimental study would be made under the auspices of UNRRA in order to ascertain the value of the pro-

cedure so as to permit the eventual official recognition of the Dakar method of immunization in the matter of international sanitary regulations.

This experiment took place in France

TABLE 1
*Yellow Fever Vaccinations by Scarification
Civilian Population*

(Total French West Africa and Togo)

Population = About 16 Million Inhabitants

	<i>Simple Vaccine</i>	<i>Mixed Vaccines</i>	<i>Total</i>
1939	2,760	98,873	101,633
1940	64,982	232,675	297,657
1941	371,097	1,128,868	1,499,965
1942	281,468	2,585,340	2,866,808
1943	459,339	2,475,883	2,935,222
1944	391,066	3,265,510	3,656,576
1945	538,684	2,434,190	2,972,874
Total	2,109,396	12,221,339	14,330,735

NOTE: The total, taken on December 21, 1945, of the yellow fever vaccinations performed among the Military (Navy and Air Corps included) amounted to 232,357.

in July, 1945, in accordance with the protocol drafted by the experts of the Quarantine Commission and accepted by the French sanitary and military authorities. It was performed on 600 men of a division destined for the French Expeditionary Corps of the Far East. The men chosen had never been out of France nor had they ever been submitted to any vaccination against yellow fever. Their ages varied from 21 to 30 years.

The subjects were divided into three groups, as follows:

Group A: To be immunized by scarification with yellow fever vaccine prepared by the Pasteur Institute of Dakar.

Group B: To be immunized by scarification with the Dakar yellow fever vaccine mixed with the vaccine against smallpox.

Group C: To be immunized by hypodermic inoculation with vaccine 17-D.

All of the said operations were performed in the presence of representatives of the UNRRA Commission.

The reactions were very carefully observed. It was agreed that the in-

oculated men should continue to lead a normal life but would, from the military point of view, be kept almost at rest for a period of one week, particularly on the 4th and 5th days after vaccination.

These prescriptions were followed in regard to the groups B and C, which showed only the usual slight reactions to such operations, namely, a rise of temperature and headache, in about 10 per cent to 12 per cent of the cases.

On the other hand, the men constituting Group A, due to some misunderstanding, were subjected to a severe physical effort which included a march on foot of 15 kilometers on hilly terrain and a stop of several hours in the hot sun. This fact presumably was responsible for the reactions observed on the 4th and 5th days, which were much more numerous—up to 35 per cent of the subjects. No serious reaction, however, was registered.

As regards the results of the vaccination against smallpox (Group B), 36 definite reactions characterized by the development of vesicles, were noted. We thus had 16 per cent of positive results, which is indeed a very good proportion since all the subjects had already been vaccinated against smallpox several times before. The vaccine used was the dried vaccine of the Institut de Vaccine de Paris (Vaccine Institute of Paris).

In order to determine the results of the yellow fever vaccination, blood samples were taken 35 days after inoculation. Moreover, blood serum was obtained also from 30 non-vaccinated men of the same regiment who had never been out of France.

Each sample of serum was divided between three ampoules, of which one was destined for the Pasteur Institute of Dakar, and the other two for UNRRA. The laboratories did not know the origins of the sera.

Finally, UNRRA announced that on

the subjects who had received the yellow fever vaccine of Dakar alone, the sero-protection test had been positive in 98.94 per cent of the cases. On the subjects that had received the yellow fever vaccine of Dakar and the vaccine against smallpox at the same time, the sero-protection test was positive in 97.93 per cent of the cases.

Consequently, in accord with the opinion expressed by the Quarantine Commission, the Standing Technical Committee on Health of UNRRA unanimously decided to acknowledge the validity of the vaccine of the Pasteur Institute of Dakar from the international standpoint.

The following are the details of the preparation and utilization of the vaccine:

1. *Preparation of the Vaccine—*

The virus used is of the French strain which has actually been carried to the 256th–258th passage in mouse brain. A dried mouse brain preserved in vacuum and cold storage is finely ground up in 5 ml. of physiological salt solution. The resulting suspension is centrifuged and the supernatant fluid is inoculated in doses of 0.03 ml. into as many mice as necessary. Only those mice that show definite paralysis on the 4th and 5th days after inoculations are sacrificed. The brains are then removed. Controls for sterility are made by inoculating culture media under aerobic and anaerobic conditions. Each brain is placed in a numbered small glass tube placed in a refrigerator at -25°C .

When all the brains have been removed and frozen, they are placed in a vacuum chamber with calcium chloride and put into the refrigerator at -25°C . The vacuum chamber is connected with an oil pump which produces a vacuum and permits perfect desiccation after a period of 3 to 4 days.

The dried brains known to be sterile are very finely ground in a mortar, alone

at first, and then with infusorial earth, to which powdered Kaolin is later added. To one measured volume of brain powder two volumes of sterile inert powder are added. The mixture thus obtained is again dehydrated under vacuum at -25°C . for 24 hours. A second test for sterility is made.

The powder, verified sterile, is then divided between ampoules with the aid of a measuring spoon. Each measuring spoon corresponds to 1/10 of a brain and represents 100 doses of vaccine, each whole brain thus giving 1,000 doses of vaccine. The vaccine titer is the amount which will kill a mouse with regularity at a dilution corresponding to one part fresh virus in one million parts.

The ampoules of vaccines, sealed under vacuum, are stored at a temperature of -4°C . The potency of the vaccine persists for 2 months after leaving the laboratory, provided it is kept in an icebox. The vaccine may be transported at ordinary temperatures, if for not more than several days.

2. *How to Use—*

At the moment of using, the contents of an ampoule of 100 doses is poured into a mortar. There is then added, drop by drop, 2 ml. of a gum solution, stirring continuously with a shaker. The gum solution has proved to be far superior to glycerine. In fact, the gum is much less fluid and dries rapidly. After two to three minutes, a thin film is formed which keeps the virus fixed upon the scarified region. The solution used is of gum arabic harvested in Senegal, saturated, rigorously neutralized, filtered, and sterilized.

For the mixed vaccination, the anti-smallpox vaccine virus most generally employed is the dried vaccine prepared by the Vaccine Institute of Paris. The two viruses are carefully mixed in the mortar before the admixture of the gum solution.

The precautions to be taken at the gatherings for vaccination are the same as those recommended for the practice of Jennerian vaccination in the tropical regions. The vaccination campaigns ought to be carried out, as far as possible, during the least hot seasons, at the first hours of the day and *always* in the shade.

With the vaccine style, two drops of vaccinal suspension are deposited on the deltoid region. Through each drop, two parallel scarifications of 0.5 cm. in length are made. Surveillance of the vaccinated persons should be exercised for about 5 minutes to make sure that they do not wipe off the vaccine. When the gum has dried entirely, the surveillance may cease.

It is, therefore, evident that the operation is very simple, requiring a minimum of material, and that it can be carried out in the shortest space of time. Finally, this method of scarification is in general well accepted by the African population, who, on the other hand, often fear the subcutaneous injections.

Those are the reasons that assured the success of the method of the Pasteur Institute of Dakar. French Africa is beginning to reap the fruits of the effort. The cases of recognized yellow fever have progressively decreased despite the regular investigations made concerning all febrile affections more or less suspected and the practice of viscerotomy.

Thus there were 17 confirmed cases in 1941, 10 in 1942, 12 in 1943, 2 in 1944, only one doubtful case in 1945, and none at all during the first semester of 1946. Among these cases of yellow fever, 6 were in individuals who were supposed to have been vaccinated by the Dakar method.

It is probable that almost all of these cases have to do with persons hostile to the vaccination who deliberately wiped off the vaccines immediately after the

scarification. In the majority of the cases the virus had been placed in suspension in glycerine and not in gum.

It is, therefore, essential that the operations of vaccination be well organized and supervised. Actually, this service is well organized and the results seem to indicate that the large majority of the inhabitants of the regions in which vaccination has been practised are definitely in a state of immunity against yellow fever virus.

An inquiry has just been made concerning the native populations of two villages of Senegal, one having been vaccinated four years ago, and the other seven years ago. For the first village, 85.9 per cent of the 106 sera taken at random showed a positive sero-protection test (after four years). For the second village, vaccinated seven years ago, there were 82 per cent positive tests among 72 sera taken.

These results of long duration obtained in the bush, far from the conditions realized in the laboratory, are excellent and indicate the confidence one may place upon the wide use of the above mentioned method, carried out with the periodicity of vaccinations every four years.

Chinese Public Health Association Is Established

The Chinese Public Health Association was organized in May, 1947, during the Nanking meeting of the Chinese Medical Association with which the new group is affiliated, although it is an autonomous association of public health workers in China, including engineers, nurses, and others outside the medical profession. P. Z. King, M.D., the Vice Minister for Public Health, was elected President, and the Secretary is Yü Huan-wen, M.D., Professor of Public Health, National Central Medical College, Nanking.

It was reported at the meeting of the association that the Chinese translation of the report on the Control of Communicable Diseases, published through

six editions by the American Public Health Association, had been translated into Chinese. This report has been adopted as an official statement by the National Health Administration of China. It was recalled that much of the text of this report had been prepared in agreement with representatives of the medical staff of the British Ministry of Health, that the epidemiologic information contained in the report had been approved for distribution through U.N. R.R.A. channels, that the text had been approved in principle by the American Red Cross, and by the Surgeon General, United States Army, and that it is official with the U. S. Public Health Service and United States Navy.

Allergy in Brucellosis*

ALBERTO P. LEÓN, M.D., M.P.H., F.A.P.H.A., AND
JOSÉ SOSA, Q.B.P.

*Laboratory of Bacteriology and Immunology, Institute of Health and
Tropical Diseases, Mexico City, Mexico*

SINCE the work of Fleischner and Meyer¹ in 1918, and of Burnet² in 1922, it was established that *Brucella* infections, like tuberculosis, elicit a state of allergy which can be detected by an intradermal reaction with bacterial extracts, as did the former, or with broth culture filtrates, as did the latter of these authors. Burnet found that this reaction could be used for the diagnosis of brucellosis, and this finding was confirmed by many authors after him. Tapia and del Valle³ in 1928, by making a comparative study in cases of brucellosis and controls, observed that *Brucella* suspensions could be used for the same purpose and that this antigen was probably more specific. A complete review of the literature on this subject has been made by Leavell and Amoss⁴ up to 1931, to whose paper the interested reader is referred. The bacterial suspension was found to be a superior antigen to the broth culture filtrate, in the diagnosis of brucellosis, by Mitra,⁵ Fornaco and Bua-Fazio,⁶ de Fermo,⁷ Giordano,⁸ and others. Leavell and Amoss (*loc cit.*) made intracutaneous tests in a small group of cases of undulant fever and in controls using as antigens bacterial suspensions, saline bacterial extracts, a soluble substance prepared according to the methods described for streptococci by Lancefield,⁹ and Ando,¹⁰ and a broth culture filtrate. They concluded that heat-killed

bacterial suspensions seem to have more specific action than bacterial filtrates. Notwithstanding, several authors have preferred to use bacterial antigenic fractions rather than the whole bacterial cell for the skin test in the diagnosis of brucellosis. Huddleson, Johnson, and Hamann¹¹ have employed the nucleoprotein fraction which they call brucellergen. This substance has been used by Keller, Pharris, and Gaub,¹² by Angle, Algie, Baumgartner, and Lunsford,¹³ by Memfee and Poston,¹⁴ and by others with satisfactory results. Some authors have objected to the use of bacterial suspensions because of the severe reactions which are induced, particularly the abscess formation at the site of the injection. This in our opinion is due to the large doses which have been employed.

Yeckel and Chapman¹⁵ have used concentrations as turbid as No. 1 of the nephelometer of barium sulfate; McBryde, Daniel, and Poston¹⁶ used bacterial suspensions standardized by comparison of turbidity with the 1:1,000 U. S. Public Health Silica Standard diluted farther 1:15; Goldstein¹⁷ has employed a suspension with 500 million bacteria cells per ml.; Favorite¹⁸ used suspensions with 800 and 80 millions per ml., and Angle, Algie, Baumgartner, and Lunsford (*loc. cit.*) 600 million per ml. It seems to us that these doses have been taken arbitrarily, without any previous study which would justify them. It appears to us also, that in any studies of allergy in infections, the antigen used should

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946

be as complete and natural as it is found in the living bacterial cell if we want to have a complete picture and not to miss some of the qualitative and quantitative characteristics of the phenomenon. For these reasons we have engaged in studies of allergy in brucellosis to the whole bacterial cell, as a contribution to the knowledge of this very important problem. Our study undertakes several points that we consider interesting both from the practical and from the purely theoretical points of view. These are:

1. The sensitization and character of allergy of laboratory animals experimentally infected or injected with dead *Brucella abortus* and *melitensis*.

2. The frequency of positive skin reactions to different concentrations of *Brucella* suspensions in supposed normal persons and in proved cases of brucellosis. The results of this part of the study would enable us to fix the proper dose to detect *Brucella* allergy in infected persons

3. The differences of skin reactivity to *Br. melitensis* and *abortus* in cases of brucellosis. The results of this study would enable us to decide whether it is possible to distinguish the species of *Brucella* in a case by means of the allergic skin reaction.

4. The intensity of the allergic skin reaction at different periods after the onset of the disease and its fate after repeated specific stimulus with various intradermal doses of bacterial suspensions, and the influence of these on the course of the disease.

This would enable us to visualize whether it is possible to desensitize against *Brucella* and if this would have any influence on improvement and recovery of the cases.

The purpose of this paper is to describe our studies of the points mentioned, and the results obtained.

METHODS

Two antigens were used throughout our experiments. One was a saline suspension of *Br. abortus* and the other a saline suspension of *Br. melitensis*. A stock suspension in saline solution was standardized by turbidity to number 3

of the MacFarland nephelometer, having approximately one billion bacterial cells per ml. and from this ten-fold dilutions in 0.85 per cent NaCl solutions were made. The suspension with 100,000 cells per ml. was labeled dose 1, the suspension with 1,000,000 cells per ml., dose 2; the suspension with 10,000,000 cells per ml., dose 3; and that with 100,000,000 cells, dose 4. The suspensions were prepared with 48 hour cultures of smooth strains of *Br. abortus* No. 3 and *Br. melitensis* No. 2456, except for the repeated specific stimulus in cases of brucellosis, in which the suspensions were prepared with the strains isolated from each case by hemocultures. The *Brucella* were killed with formalin 0.2 per cent.

The skin reactions were made by injecting 0.1 ml. of the antigen intradermally with a 26 gauge needle and tuberculin syringe.

The reaction was read 48 to 72 hours after the injection, and classified as follows:

Edema 5 to 9 mm. in diameter + (one plus)
Edema 10 to 19 mm. in diameter ++ (two plus)
Edema 20 to 29 mm. in diameter +++ (three plus)
Edema 30 mm. or more in diameter ++++ (four plus).

For the study of the frequency of positive skin reactions to different concentration of *Brucella* suspensions in supposed normal persons, and in proved cases of brucellosis, doses 1, 2, and 3 were injected each into different groups of normal persons. In cases of brucellosis, dose 1 was used first; if it was negative, dose 2 was injected; and if this was still negative, dose 3 was used 7 days later.

For the study of the differences of skin reactivity to *Br. melitensis* and *abortus*, both antigens were used. One antigen was injected into the right forearm, and the other into the left forearm of proved cases of brucellosis var.

melitensis or at different sites of experimentally sensitized guinea pigs. Dose 2 was used; if the reaction was negative or if no difference was observed between the reaction to both antigens, then dose 3 was injected. The diameter of the erythema and edema of the reaction to both antigens was measured in mm. The average reactions and the percentage giving any difference were calculated for all cases studied.

For the study of the intensity of the allergic skin reaction at different times after the onset of the disease, we skin tested with dose 2 of *Brucella melitensis* several groups of cases of brucellosis which were at different periods of the disease. The size of the edema in the largest diameter in positive reactors was measured and the average for each group calculated.

For the study of the fate of *Brucella* allergy in brucellosis after repeated specific stimulus, we injected into the skin of 35 patients with brucellosis several and repeated doses of the homologous antigen to the species of *Brucella* infecting the case, if this was isolated and identified, or to the antigen giving stronger reaction. We started the injections with the smallest dose giving ++ reaction and when the reaction to the previous injection had disappeared repeated it as many times as necessary for this dose to give a one plus or less reaction; then we continued with the next stronger dose, and so on until the case recovered, or up to 20 injections were given. A numerical value was given to each type of reaction for each dose of antigen; the smallest numerical value (1) was given to the weakest type of reaction (+) to the largest dose of antigen (dose 4); the next numerical value (2) was given to the next stronger type of reaction (++) to the same dose, and so on, until the largest numerical value (16) was given to the strongest reaction (++++) to the smallest dose (dose 1). With these

numbers were calculated the average numerical values for the observed reactions to the doses of antigen injected after a given number of injections were received in each case, as well as the average numerical values of the average values of the reactions observed in all the cases receiving up to the stated number of injections. Then the corresponding type of reaction for the corresponding dose of antigen to this average numerical value was obtained. In this way the average intensity of the observed reactions after receiving up to any number of injections of any dose of antigen was estimated for all the cases studied, thus giving the picture of the fate of the allergy after repeated specific stimulus with various intradermal doses of bacterial suspensions.

The influence of the repeated specific antigenic stimulus on the course of the disease has been only estimated by the improvement in symptoms, the gain in weight and strength, and the more or less rapid recovery of the cases. No controls were observed to estimate whether or not the length of the disease was significantly shortened. Any conclusion in this respect will not be based on statistical analysis but rather on clinical impression.

For the study of sensitization of laboratory animals we infected 4 guinea pigs, 2 with *Br. abortus* and 2 with *Br. melitensis*, by the subcutaneous route and with 0.5 ml. of a 24 hour broth culture. We also injected 4 rabbits with 8 progressive doses of 0.1 to 1 ml. of a *Brucella* suspension with one billion cells per ml. The injections were given at 4 day intervals. Two rabbits were injected with the *Br. abortus* antigen and two with the *Br. melitensis* antigen. Every 15 days after the last injection all rabbits were skin tested each with doses 2, 3, and 4 of *Br. abortus* and *melitensis* antigens. Two female rabbits were passively sensitized by the injec-

tion of 2 ml. of blood serum of one of the rabbits actively sensitized as has been described. Twenty-four hours later they were sacrificed and one of the uterine horns was used for the hypersensitive test following the Dale technique. Tyrode solution was used as the isotonic medium and 0.1 ml. of *Brucella* suspension No. 3 as the inciting allergen.

RESULTS

Sensitization of laboratory animals—Guinea pigs experimentally infected with *Brucella abortus* or *melitensis* gave one month later a negative reaction to the skin test with dose 2 of *Brucella* suspensions, to dose 3 a + reaction, and to dose 4 a ++ reaction. No difference was observed between the reactions to the same doses of *Br. abortus* and *melitensis*.

The rabbits actively sensitized with suspensions of dead *Brucella* reacted negatively to the skin test within 1 month of sensitization, but 1 to 2 months later they gave positive skin

reactions. The type of reactions were: + reaction to dose 2; ++ reaction to dose 3, and +++ reaction with nodule to dose 4. The reactions were always larger for the homologous antigen, the difference being about 2 mm. for each ten mm. diameter of reaction with the heterologous.

The uterus of passively sensitized rabbits reacted to contact with *Brucella* suspensions by contractions that appeared after a period of incubation of 20 to 22 minutes. There was not any apparent difference between the response to the homologous and the heterologous antigen. The reaction was highly specific as shown by control tests.

Frequency of positive skin reactions in normals and in cases of brucellosis—The results on the frequency of positive skin reactions to different concentrations of *Brucella* suspensions in 298 supposedly normal persons and in 78 proved cases of brucellosis are given in Table 1. As shown in this table, dose 2 gave the greatest difference between the frequency of positive skin reactions in

TABLE 1
Frequency of Positive Skin Reactions to Different Concentrations of *Brucella* Suspensions in Supposedly Normal Persons and in Proved Cases of Brucellosis From 3 to 22 Months After Onset

¹ All negative reactors to dose 2 were positive to dose 3 at the time of this reaction or later.

cases of brucellosis (89 per cent) compared with normal persons (8 per cent). The intensity of the local reactions was about the same with dose 1 and 2 in positive reactors, but was much stronger with dose 3. No general reactions were observed with dose 1, 40 per cent general reactions occurred with dose 2, and 50 per cent with dose 3 in positive skin reactors.

Of the 47 "normal" persons who gave positive skin reactions to any of the *Brucella* suspensions, 20 were studied further to detect actual or past *Brucella* infections. Of these, 6 gave positive agglutination reactions from 1:25 to 1:50; 17 were classified as susceptible, and 3 as immunes according to the Huddleson, Meyer, Gould, and Paulson¹⁹ opsono-phagocytic index.

Most of these supposedly normal persons with a positive skin reaction gave a history suggesting past or present *Brucella* infection.

Differences in skin reactivity to Br. melitensis and abortus in cases of brucellosis—The results on the differences in skin reactivity to *Brucella abortus* and *Br. melitensis* in cases of brucellosis var. *melitensis* are tabulated in Table 2. It is shown in this table that more than 70 per cent of the cases gave a stronger reaction to the homologous antigen. With dose 3 the difference in reactivity was shown in a larger percentage. As similar results had been obtained in experimentally sensitized rabbits it is felt that the diagnosis of the species of *Brucella* can be made by the skin test with suspensions

TABLE 4

² Intensity of reaction to dose 3 (1,000,000 organisms).

of *Brucella abortus* and *Br. melitensis*.

The intensity of the allergic skin reaction at different times after the onset of the disease—The results on this point are tabulated in Table 3, and the scheme of the type of reactions in Plate I. As shown in this table, allergy to *Brucella* suspensions in brucellosis seems to appear after one month has elapsed from the onset of the disease and to increase thereafter with time; as more time elapses the reactions are stronger. We have seen cases 5 to 25 years after the onset of the disease with +++ positive skin reactions to dose 2 of *Brucella* suspensions.

The fate of Brucella allergy after repeated specific stimulus—The results

of our studies on this point are tabulated in Table 4 and a scheme is given in Plate II. It is shown in this table that the allergy decreases as the specific stimulus is repeated, arriving to a state, after 16 to 19 injections have been given, in which a one plus reaction is observed with the highest dose of antigen we have used, dose 3. This desensitization only occurs when the specific stimuli are started 6 months or later after the onset of the disease. When these are started within 6 months of onset the allergy increases up to a ++++ average reaction to dose 3 of our antigen in the same period. As the injections of antigen were given at weekly intervals, it can be seen that in

PLATE NO II
ALLERGY IN BRUCELLOSIS TO BRUCELLA SUSPENSIONS
AVERAGE SKIN REACTION TO BRUCELLA AFTER REPEATED
SPECIFIC STIMULUS

less than 5 months the allergy increased or decreased notably under the influence of the repeated specific stimulus, something that is very different from what occurs normally with allergy in cases of brucellosis, as shown in Table 3 and Plate I.

The influence of repeated specific stimulus on the course of the disease—The results of our study on the influence of repeated specific stimulus with various intradermal doses of bacterial suspensions on the course of the disease, are summarized as follows:

Of the 15 patients desensitized with several doses of *Brucella* suspensions, 5 recovered when desensitization was achieved, that is, when 16 to 19 injections were given. Seven recovered before desensitization was reached, when 8 to 18 injections were given, and 3 improved but suspended treatment before complete recovery. The 20 patients in which allergy increased have improved notably; 14 are still under treatment and the others suspended it before recovery. The clinical impression is that cases of brucellosis recover in from 2 to 5 months when they are desensitized under the influence of repeated specific stimulus in this lapse of time, and those which are not desensitized in this same lapse of time improve notably while under repeated specific stimulus, but will take longer to recover as well as to be desensitized.

SUMMARY AND CONCLUSIONS

Formalin killed saline solution suspensions of *Br. abortus* and of *Br. melitensis* have been used in the study of allergy in supposedly normal persons and in proved cases of brucellosis in doses of 0.1 ml. of concentrations from 100,000 to 10,000,000 organisms per ml. injected intradermally. *Brucella* allergy in experimentally sensitized guinea pigs and rabbits was also studied. In these laboratory animals positive skin reactions to *Brucella* suspensions were

observed one month or more after previous sensitization; in guinea pigs the reaction was the same to the homologous or the heterologous *Brucella* antigen, while in rabbits the reaction was stronger for the homologous specific antigen. Female rabbits were passively sensitized, and the uterus gave a positive Dale reaction. In supposedly normal persons the skin test was positive to the 10,000 bacteria dose in 6.4 per cent; to the 100,000 bacteria dose in 8.5 per cent, and to the 1,000,000 bacteria dose in 26.1 per cent. In proved cases of brucellosis the reaction was positive in 41.6 per cent with the first dose, in 88.8 per cent with the second dose, and in 100.0 per cent of the cases with the third dose. The skin reaction was stronger to the homologous specific antigen in 71 per cent of the cases with the third dose and in 56 per cent with the second. In the cases studied, the allergy to *Brucella* suspensions appeared after one month had elapsed from the onset of the disease, and increased thereafter until the strongest reactions were observed more than 5 years later. The allergy in cases of brucellosis decreased as specific repeated stimulus progressed, arriving to a state, after 16 to 19 injections were given, in which a very weak reaction was observed to the strongest dose we used. This desensitization occurred only when the specific stimulus was started 6 months or later after the onset of the disease. Patients with brucellosis recovered in from 2 to 5 months when they were desensitized under the influence of repeated specific stimulus by the intradermal injection of *Brucella* suspensions; patients who were not desensitized in this same lapse of time improved notably.

Based on the foregoing results we arrive at the following conclusions:

1. Laboratory animals are actively sensitized either with dead or living *Brucella* suspensions, and passively sensitized with sera of previously sensitized animals.

2. Suspensions of formalin killed *Br. abortus* or *Br. melitensis* seem to be adequate antigens for the detection of allergy in brucellosis. The proper initial dose for this purpose is 0.1 ml. of a suspension with one million bacterial cells per ml. injected intradermally. If the reaction is negative a second injection with a suspension ten times stronger is indicated. A positive reaction is obtained in all or almost all the allergic cases without undue local or general reactions.

3. The diagnosis of the species of *Brucella* between *melitensis* and *abortus* is possible in a large percentage of the cases of brucellosis by the allergic skin test if the two antigens, in the same concentration, are injected at the same time in different sites. The reaction is stronger with the homologous antigen.

4. Allergy to *Brucella* in cases of brucellosis seems to appear one month or more after the onset of the disease and to increase thereafter indefinitely.

5. By repeated specific stimulus with intradermal injections of small and increasing doses of the homologous *Brucella* suspensions, all cases of more than 6 months' duration can be desensitized in from 2 to 5 months. Cases of less duration will take longer.

6. By means of these repeated intradermal injections of increasing doses of the homologous *Brucella* suspensions, all brucellosis patients who become desensitized improve, and most recover within 2 to 5 months of treatment. The ones which are not desensitized in this time will take longer to recover.

THE HEALTH OFFICER AND THE HEALTH COUNCIL

THE day of defensiveness in public health has gone by. The health officer has no longer the need to protect his rights and his prerogatives. If he be a trained man, he will find himself recognized without question as the leader of the health program of his area. His problem is an offensive one—the visualization and execution of an ever-widening program for applying our knowledge to the promotion of health in a positive sense.

The health officer should be the chairman of the Board of Strategy for this campaign; but he and his staff cannot wage the war alone. When the health program envisaged only sanitation and the control of epidemic diseases, the official agency could perhaps do the whole job. But today, when the urgent health needs are for housing and nutrition and medical services, for care of chronic diseases, for mental hygiene, for health education, it is clearly impossible to attain major results without a widespread and vital public understanding and support.

We have seen the power of community participation during recent months in the triumph of the health-district plan in Illinois and in the revolution worked under the stimulus of Dr. Florence Sabin in Colorado.

One of the best ways to realize the pulse of progress is to attend a conference of health workers and see what they are thinking about. At a recent meeting of the New England Health Institute in Durham, N. H., the keynote of one speaker after another was the need for wider community participation in the public health program; and it was made clear that "participation" meant just that. Some health officers, who have come only part way out of their shells, consider that what they need is a cheering section, ready to respond with vociferous advocacy of any measure they, as cheerleaders, may indicate. Beyond the ivy walls, human nature does not respond—or only sporadically responds—to such an appeal. Continuous and convinced support implies an understanding of a problem and a sense of sharing in finding the solution.

None of us has all the answers. The man on the spot is inevitably limited by tradition and habit. Rare is the executive who does not sometimes feel—if he does not say—"It's always been done that way here." Nor has the outside expert, called in for counsel, any ready-made solution. If he is an experienced surveyor he talks with everyone, inside and out, who is in a position to evaluate either the

delivery or the receiving end of public health services. From such conferences, in the light of general principles, on the one hand, and local situations and local personalities, on the other, he formulates a tentative program of advancement; and if he sells it to the lay people, something may happen. The ideal result is only attained when the leaders in all the official and voluntary agencies concerned organize themselves for a comprehensive and continuing self-survey.

Such a type of coöperative program planning is the objective of a well conceived Health Council; and that is why we asked Mr. Bleecker Marquette to prepare the Special Review Article for this issue of the *Journal*.

Mr. Marquette points out the results which are manifest in a community where there is no health planning. He shows how a good Health Council should be organized and what it can accomplish. He points out that there are only as yet a score or so of active Health Councils in this country; and that only a few of them are really fulfilling their function well. The Health Council is a relatively new idea; but it is a sound idea and one that is full of promise.

Do you really know how effectively the activities of the health department and the board of education in your community are correlated so as to produce maximum results in the education of the individual child and his family? Is the sanitary inspection service of the health department tied in with the efforts of a local housing authority so that condemnation and compliance orders may fit into a plan, and so that the provision of good housing may keep pace with the elimination of bad housing? Are there adequate community facilities for the rehabilitation of the tuberculosis cases which you send to a sanatorium? Are the services of the various public health nurses of your area coördinated into the most effective practicable pattern? How inadequate are the institutional provisions for the care of chronic illness, and what ought to be done about it? Are the services of venereal disease control supplemented by a decent community recreation program? Is your local safety council putting all its energies into industrial plants and neglecting the much larger problem of home safety? How many hours of child guidance service are available in the community, and how many hours of service at mental hygiene clinics for adults? (The writer knows of two New England cities of the same approximate size where the latter figure is in one case 6 and, in the other, 43.)

These are examples of some of the vital health problems which confront us. They are the problems with which the Biggses and the Chapins of the future will successfully contend. But they cannot solve them singlehanded. Such questions can be answered only by real coöperative effort, by enlightened and continuing program planning. In a good Health Council, under the leadership of a good health officer, lies the hope of the future.

PLANNING FOR THE CONTROL OF STREAM POLLUTION

A RECENT issue of the *Journal of the New England Water Works Association*, presents an interesting symposium by official representatives of the six New England states on the important problem of stream pollution abatement.¹

The most fundamental necessity in this field is, of course, the prevention of pollution with intestinal bacteria of lakes and inland waterways which are used as sources of potable water, or by bathers, to an extent which threatens to produce epidemic or occasional case of communicable disease. This basic end has been partially attained in the area in question. It is doubtful if any appreciable

amount of typhoid fever or any other intestinal disease can be attributed to water in the New England States. It is somewhat disconcerting, however, to learn from E. L. Tracy, one of the participants in the symposium we are reviewing, that only 6 per cent of the sewered population of Vermont and less than 3 per cent of the total population of that state, are served by sewage treatment plants.

The problem, however, is much wider than protection against the germs of water-borne disease. Health is an ideal which is not attained merely by escaping typhoid fever. Recreation is an important factor in health as a positive objective, and esthetic satisfaction cannot be omitted from an adequate concept of healthy living. Our lakes and streams are among our most priceless community assets; and to permit them to become open sewers or offensive disposal tanks for factory wastes is a short-sighted policy.

Obviously, the problem is incapable of any simple universal solution. L. W. Trager points out that the conflicting issues are presented with special clearness in New Hampshire. This state has two major assets—its recreational facilities and its industries; and the two interests are directly opposed to each other in their views on stream pollution. In certain streams, the process of pollution has gone so far that the water could only be restored to recreational use at a prohibitive cost which—whether expended by the state or by industry—would ultimately be passed on to the consumer. In such a case, nothing can be done except to keep the resulting nuisance within bearable proportions. In other areas, the value of residential and recreational property is so great that it is clearly to the economic interest of the community as a whole to insist on high standards of purity.

A primary question in any given state, concerns the designation of the proper state authority to make decisions in regard to this problem of local standards for each individual watershed. Among the states included in the New England symposium, responsibility rests with the State Board (or Department) of Health in Massachusetts, Rhode Island; and Vermont. In Connecticut, the task is divided between the State Department of Health (concerned with health aspects of pollution of potable waters, bathing waters, and shellfish-growing areas) and the State Water Commission (concerned with broader phases affecting fish life, use of water for industry, damage to property, and interference with navigation). W. J. Scott of the Health Department, reports close coöperation between the two state agencies; but the maintenance of two boards and two laboratories in such closely related fields does not seem in accord with sound administrative policy. A more logical procedure was in force in earlier years in Connecticut, which centralized technical work in the Health Department and provided an Industrial Wastes Board, including representatives of the Health Department, industry, and the public, to formulate policies. Maine also has a separate State Sanitary Water Board, established in 1941, and New Hampshire has a separate Water Pollution Board, each with its own laboratory. In New Hampshire, the State Water Pollution Commission includes the State Health Officer with representatives of the Governor, the Forestry and Recreation Department, the State Planning and Development Commission, the Fish and Game Department, the Water Resources Board, and representatives from industry and municipalities. The Director of Sanitary Engineering of the State Health Department serves as technical secretary. A plan of this general type seems highly desirable. The basic objective is health in the broad sense; but the problems are too complex to be solved by the Health Department alone, without the voice of spokesmen for the broader social and economic issues which are involved.

Most of these New England States have rightly conceived their first task to be the mapping out of the state so as to define what may be considered a reasonable objective for each individual watershed. In Maine 6,000 miles of inland waters have already been surveyed and classified under the usual four main headings as follows:

Class A—Drinking water sources or waters used for growth of market shellfish

Class B—Waters used for bathing

Class C—Waters used for recreational boating, fishing, seed oyster cultures, or industrial supply after treatment

Class D—Waters used primarily for navigation or transportation of wastes without nuisance

The New Hampshire Board states its objectives in this regard as follows: "To classify streams, lakes and tidal waters (a) according to present highest use (present condition and use), and (b) according to potential highest use, being mindful of the industrial, economic, geographic, and social factors." Its State Water Commission has been materially strengthened by the 1947 Legislature. In Vermont, the Health Department organizes each major river basin (of which there are 12 in the state) by holding a mass meeting, in coöperation with the State Chamber of Commerce, in the largest municipality of the area. At this meeting a river-basin committee or sanitary council is formed with representatives from each individual town; and subsequent meetings are arranged to reach smaller local areas. This seems like an admirable instrument of public health education.

A. D. Weston cites some highly interesting results from the studies made along this line in Massachusetts. One stream, on which there is a large recreational basin, fulfils the standards for Class B on the average (less than 1,000 coliform organisms per 100 ml.), but has at times shown a coliform density of over 100,000 per 100 ml., so that its beaches have had to be closed for bathing. Another stream, generally considered as of high purity, has on some occasions shown over 10,000 coliforms per 100 ml. as a result of unapproved sewers in villages where even the existence of such sewers was not generally known. Mr. Weston claims for his state "one of the most, if not the most highly polluted streams known," with a biochemical oxygen demand once attaining the level of 1,420 p.p.m.

It is most encouraging to see that the basic knowledge of conditions, essential to a rational system of control, is being accumulated so effectively in such states as those which have been cited. Actual progress in bringing desirable standards into effect is still, however, not far-reaching. The state departments of health have ample powers to safeguard waters of Classes A and B by forbidding the use of non-conforming streams or lakes for water supply or bathing or the taking of shellfish and by forbidding bathing or other pollution of established public water supplies. In Connecticut, the state law is so strict as to forbid bathing even in remote tributaries of such supplies, to a degree which unreasonably interferes with normal recreational use. With regard to nuisance problems and—in particular—Class C stream, or an actual Class C stream into a potentially Class B stream, accomplishments have not as yet been notable.

Statutory powers of enforcement are in some instances far-reaching. In New Hampshire, all natural lakes having an area of 20 acres or more ("Great Ponds") "are public waters, and are held in trust by the state for public use; and no corporation or individual shall have or exercise in any such body of water any

rights or privilege not common to all citizens of this state." Under a 1947 Act, all wastes discharged into such ponds must be adequately treated and disinfected.

The State Water Commission of Connecticut is empowered to make orders after hearing, directing any person, firm, or corporation to use or to operate some practicable and reasonably available system or means which will reduce, control, or eliminate pollution, having regards to the rights and interests of all persons concerned, provided the cost of installation, maintenance, and operation shall not be unreasonable or inequitable.

Massachusetts has an even stronger law, providing that the State Department of Health with the approval of the Governor and Council shall "prescribe and establish rules and regulations to prevent pollution or contamination of any or all of the lakes, ponds, streams, tidal waters, and flats within the Commonwealth." Such rules and regulations were formally prescribed and approved in September, 1945. These regulations are far-reaching. They provide that no excremental matters or house wastes, or garbage and manure, and no manufacturing waste or putrescible animal matter shall be discharged into any lake, pond, stream, tidal water, and flat "in a manner which may be injurious to the public health, or may tend to create a public nuisance, except as may be approved by the Department of Public Health when in the opinion of said department the best practicable and reasonably available means to render harmless such refuse, waste product, polluting liquid, substance, putrescible organic matter, or wastes have been provided in accordance with plans approved by the department." This is strong medicine; and, in 1946, four municipalities and several industries were actually brought into court on charges of nonconformance.

In Maine, a law was passed providing that all new industries, established after July 24, 1945, must have a license to discharge industrial wastes into any body of water; but no machinery has been provided for dealing with existing industries.

In Rhode Island the State Health Department has power to compel the elimination of pollution and has done so in certain cases. Mandatory legislation for control of pollution was sought in Vermont in 1943, but "so amended before passage that it practically legalized pollution instead of preventing it." A bill introduced in the 1947 session established a new water conservation board which should produce results. In this state, and in Rhode Island (where a new program has been recently adopted), the authorities are seeking to pave the way for treatment of municipal sewage by laws legalizing service or rental charges to finance bonds for sewage treatment.

All of the New England States except Maine (whose streams flow directly to the sea) have taken steps—or will shortly take steps—to implement interstate action through a New England Interstate Compact Commission.

Connecticut, Massachusetts, New Hampshire and Rhode Island appear to have overall stream pollution laws with potential teeth in them; and in Massachusetts and Rhode Island these laws have been actively enforced in the broader field, beyond the protection of public water supplies. It will be of great interest to observe the Vermont approach by way of a constructive educational program.

1. Symposium by Scott, W. J., Hale, J. E., Trager, L. W., Tracy, E. L., Shea, W. J., and Weston, A. D. *J. New England Water Works Assoc.*, 61:59-87 (Mar.), 1947.

NURSING EDUCATION IS A PROFESSIONAL PROBLEM

WHENEVER a social situation becomes pressing we may look for the advocates of nostrums and cure-alls, often more deadly than the disease. The present shortage of nurses results from various causes, among which economic factors are of major importance. It is not surprising—though it is unfortunate—that this situation has tempted various committees of eminent surgeons and internists to rush into the breach with the happy idea that the remedy can be found by shortening the nurses training course and returning to the low standards which prevailed a quarter century ago.

This is a familiar phenomenon in many fields. Zealous alumni are frequently quite ready to tell college faculties how their sons should be taught. Writers in some of our leading popular weeklies have recently been pontificating about medical education and demanding that its standards should be lowered—in precise parallel with medical criticism of nursing education. Criticism in itself may serve as a useful stimulus. The unfortunate thing about recent pronouncements of medical committees is their repercussions on the reputation of the medical profession itself. The prestige of the physician must rest on the respect which the public feels for the medical expert; and when the medical expert assumes the right to dictate in a field where he is not an expert, he destroys public confidence in his wisdom in his own area.

Education is a highly technical problem, and the distinguished practitioner of medicine may be—and commonly is—a layman in the educational field. The subject of nursing education happens to have been explored in two exhaustive studies^{1,2} in which educators, nurses, hospital administrators, physicians, and public health experts coöperated. The reports of these studies have been universally accepted by all competent authorities. They rightly form the basis for our present program of nursing education. For the practitioner of medicine to ignore them is as ill-judged as it would be for a teacher to brush aside the accepted principles of medical science.

There is, however, one related aspect of the problem of nursing shortage on which the physician can—and should—make an important contribution. The training of the professional nurse is progressing along reasonably sound lines; and it has been found in all educational fields that the way to long-range increase in personnel is to raise rather than to lower standards. There are, however, real possibilities of supplementing the work of the nursing profession by the employment of trained nursing attendants, a subject which we shall discuss in a subsequent issue of this *Journal*. How large the field may be for this type of subsidiary worker—and how that field should be defined—must be carefully studied. This is not a technical problem of education but a problem of administration. It should be analyzed by joint committees of physicians and nurses in the field of private practice, by joint committees of hospital administrators and nurses in the institutional field, and by joint committees of health administrators and nurses in the public health field.

Credit Lines

FAMILIES CAN'T LIVE IN PAPER HOUSES

The Newark (N. J.) Housing Authority continues to storm the walls of community indifference in behalf of the one-third of that city's population of nearly a half million who live in substandard housing. It starts out by supposing what would happen if a third of the city's people were stricken with tuberculosis, or a third of its houses burning. In the latter instance, it says "when the ashes cooled, money and building materials would be found for the greatest construction job in the city's history . . . Bad housing is . . . no less disastrous than sickness or fire, but it isn't front page news."

If anything can make it front page news such pamphlets as this, entitled "5,580 Paper Houses," can. This number refers to the houses planned since 1944 and awaiting action on the Wagner-Ellender-Taft Housing Bill.

With excellent satirical cartoons and irrefutable logic, this is an excellent attempt at community education. It points out again the high cost of slums and the financial returns of good housing. It also announces the birth of a fifth freedom—freedom to live with in-laws.

CANCER IN NEW JERSEY ANALYZED

The New Jersey Division of the American Cancer Society (Newark) has recently published *Cancer Mortality in New Jersey, 1920-1945*. This is a statistical analysis for the entire state and county-by-county of the deaths, death rates, age distribution, organ affected, as well as an analysis of the changing age distribution of the general population. Data for the separate counties cover only the 5 years, 1940-1945.

With this analysis available no local cancer program should be delayed because of lack of knowledge of existing conditions.

ANNALS OF WESTERN MEDICINE AND SURGERY

The Western readers of Credit Lines will be particularly interested in the new *Annals of Western Medicine and Surgery* which began publication in March under the auspices of the Los Angeles County Medical Association. Its editor is Edmund Thorvald Remmen, M.D., Assistant Professor, Department of Internal Medicine, College of Medical Evangelists. With an initial circulation of 7,500, its articles will have general rather than specialized interest, because the majority of its readers are general practitioners.

WHEN AN EMERGENCY STRIKES

The May *Oklahoma Health Bulletin* tells the story of how, when the recent tornado struck the town of Woodward (population 6,000), the State Health Department was one of the first agencies on the scene, sending sanitary engineers to test the water supply, food and drug inspectors to safeguard food supplies, x-ray and laboratory technicians to aid doctors and nurses and furnish blood plasma, tetanus anti-toxin, penicillin, and typhoid vaccine. In addition doctors and nurses from the State Department of Health were on emergency call.

In this connection it is worth noting that, according to the latest information available to us, neither the town of Woodward nor Woodward County with a total population of more than 16,000 had any organized full-time local health service. Nor in fact did any of the

counties contiguous to Woodward. Thus in a real emergency the state and other agencies had to do the job that should have been the first responsibility of local official agencies.

CHILDREN'S BUREAU ANNUAL REPORT

The 34th *Annual Report* of the Children's Bureau for the year ended June 30, 1946, the last year of the Bureau's life in the Department of Labor, was published recently. This summary of a bureau devoted to the special interests of children is well worth reading for its factual information no less than for what it unconsciously reveals about the current world. Included with the report is an 11 point action program for 1947 and 1948 of the National Commission on Children and Youth. Gov't Ptg. Office, Wash., D. C.

PUERTO RICO HONORS ITS ELDERS

Patriarchs and matriarchs in Puerto Rico occupied the limelight on April 18 as their countrymen throughout the island commemorated El Dia de los Ancianos—"The Day of the Aged"—with colorful tributes and festivities. El Dia de los Ancianos has been celebrated annually in Puerto Rico since 1933, when it was designated by law as the day on which Puerto Ricans would pay particular tribute to their aged.

GROWTH OF BLUE CROSS

The Philadelphia Blue Cross reports that it now has over a million members. March enrollments were nearly 17,000, the largest single month in its 8 year history. In the first quarter of 1947, the 40,000 new members were almost double the same quarter in 1946. Due to rising hospital costs, its rates have been increased by about one-third, but benefits have also been increased.

The annual report of New York's Associated Hospital Service, recently released, shows a membership of nearly

three million. Over half a million were enrolled during 1946, representing a gain of 37 per cent over 1945. During the year more than a quarter of a million persons were hospitalized for an average of nearly 10 days per patient and at an average cost per hospital stay of nearly \$75. In 1947 both payments to hospitals and charges to members are being increased. Additional member benefits are also provided.

The Blue Cross of Philadelphia and the Associated Hospital Service of New York are among 88 similar Blue Cross plans in the United States, with a total membership of nearly 26 million persons, or something less than one-fifth of the nation's population. In presenting the annual report, Louis H. Pink, the President of New York's Blue Cross, declared that in 1946 the ground work had been laid for a more effective national Blue Cross program. "The Blue Cross plans are strong because they are local organizations—but a more effective national organization would be helpful in enlarging membership and arranging for interchange of service, broader benefits, and more effective coöperation with national employers and other health agencies."

MICHIGAN'S FIVE YEAR PLAN

To establish a pattern for other states to follow in meeting the requirements of the Hospital Survey and Construction Act, the Commission on Hospital Care made a pilot study in Michigan, recently completed. The W. K. Kellogg Foundation, as a service to the people of the state, has prepared a summary of this survey with maps showing hospital service areas and the various types of hospitals and rural health centers projected by the Hospital Construction Act.

This summary of Michigan's five year hospital plan is a good illustration of a technique for informing and persuading public opinion.

ARE DOCTORS MOVING TO RURAL AREAS?

The American Medical Association's Bureau of Information in the *J.A.M.A.* for May 17, 1947, senses a "trend of returned medical officers to move away from their recent venture in city practice to accept the opportunities of more active practice in smaller communities." A number of state maps are included to show the difference between 1946 and 1947 in the ratio of patients to practising physicians in these states. This trend will be worth watching to see whether it continues to offer a rosier outlook for medical care in rural areas.

FAREWELL TO THE SOCIAL SECURITY BOARD

The Social Security Board sings its swan song in its 11th Annual report for the fiscal year 1946. In some 100 pages it summarizes the administrative changes arising out of the President's Federal Reorganization Plan which went into effect in July, 1946, and which transferred the Board's functions to the Federal Security Administrator. Apart from the analysis of current activities, this report is valuable for its summary and recommendations based upon 11 years of experience. The report includes also a section on prepayment of medical care costs. Available from U. S. Gov. Ptg. Office, Washington 25, D. C. 25 cents.

MORE ABOUT TRAINING OF RURAL DOCTORS

In February (p. 214) we reported that Mississippi currently has a scholarship loan program for training 47 of its own citizens to become doctors and practise in rural areas of the state. Now the Mississippi State Medical Education Board has published a pamphlet, *Doctors To Come*, which tells more about this program and illustrates the story with pictures, pictographs, and illustrative charts. This ought to help those Mississippi men and women in whose

hearts burns the torch of desire to serve their fellowmen and to help those who suffer," to choose a career.

At present 60 doctors are being trained, 2 of whom will be ready to practise in 1948, 9 in 1949, and all of them by 1952 or earlier. Unfortunately only 7 are Negroes in a state whose Negro population is almost half of the total. The 60 are being trained in 11 medical schools in 7 states and the District of Columbia.

The pamphlet also has some fertile ideas for other states contemplating similar programs. Applicants and others interested should address: Mrs. Maria Voskamp, Executive Secretary, Mississippi State Medical Education Board, Room 37, North St. Building, Jackson 35, Miss.

Kentucky has also taken note of the fact that for its rural population of more than two million it has only one practising doctor for more than 2,100 persons. The Kentucky State Medical Association and the University of Louisville School of Medicine have launched a joint state-wide campaign for a Medical Scholarship Fund of \$100,000. This fund will be used for loans to students who could not otherwise afford a medical education. Students must agree to practise one year in a rural area for each year of financial aid received.

Contributions in any amount are received at Medical Scholarship Fund, 620 So. Third Street, Louisville 2, Ky.

ABSTRACTING THE WORLD'S MEDICAL LITERATURE

Excerpta Medica of Amsterdam, Holland, has undertaken a project of abstracting the world's literature in the fields of research and clinical medicine. Fifteen separate subjects, among them Public Health, Social, and Industrial Medicine, will each be covered by a monthly journal published in English. The editorial board of each journal is comprised of authorities from many

countries, including liberal representation from the United States. The series will replace the old German Zentralblätter and Berichte series which will not be revived.

Vol. I No. 1 of Section XIII, on Dermatology and Venereology, April, 1947, has been received by Credit Lines. It abstracts 289 articles under 25 different subheadings of the main subject. Its board of 25 editors represents 12 European countries and the United States.

The yearly volumes for the various sections will range from 600 to 1,800 pages, and the annual subscriptions from \$15 to \$45. Section IV on Public Health, Social and Industrial Medicine will aggregate 900 pages annually and has a subscription price of \$22.50. Williams & Wilkins Company, Baltimore 2, Md., are sole agents for the United States, Canada, and Central America. A free booklet describing the series is available from the agents on request.

MAYORS TAKE A STAND ON HOUSING

The United States Conference of Mayors has published *America Can Not Afford Slums*. This is a graphically illustrated pamphlet emphasizing what has come to be increasingly recognized, that slums are a far greater drain on a community's resources by way of the costs of ill health, police and fire protection, unpaid taxes, and many other liabilities, than the public subsidies necessary to provide decent housing for the lowest income groups. This is over and above the fact that a slumless city is much more attractive than one with slums. This is good material for educating your city fathers, particularly if they are penny-wise and pound foolish. You will like it also for its excellent printing, typography, and photography. Published by the United States Con-

ference of Mayors, Washington, D. C.

WORTH ACQUIRING

What You Can Do About Tuberculosis—This manages to be new and interesting even though it must of necessity tell the old, old story of preventing tuberculosis. In blue and white and with humorous little mannikin line drawings, it might capture the interest of someone who had hitherto turned a deaf ear. Available from Life Conservation Service, John Hancock Mutual Life Insurance Company, Boston 17, Mass. Also worth while is a one page list of health publications still in print and available, in limited quantities, from the Company.

Rabies: A Challenge to the Community—Using pastel shade illustrations that have almost come to be the Lederle trade mark, this is intended for the use of the health officer and veterinarian in organizing community programs for rabies control. Because rabies strikes only rarely, says the announcement, community indifference is the rule and can be corrected only by adult education. Copies may be secured from Rutledge W. Howard, Director of Professional Service, Lederle Laboratories, 30 Rockefeller Plaza, New York 30, N. Y.

The Hospital Act and Your Community—Local responsibility is the keynote of this pamphlet by the Division of Hospital Facilities, U. S. Public Health Service explaining the Hospital Construction Act and how it works. In simple language and excellent cartoons it brings home the message that "community freedom and community responsibility go hand in hand." It is an excellent illustration of "bureaucrats" stepping down in favor of the citizenry, as well as of health education of a high order. Available from U. S. Public Health Service, Washington 25, D. C.

BOOKS AND REPORTS

*All reviews are prepared on invitation. Unsolicited reviews cannot be accepted.
All books reviewed in these columns may be purchased through the Book Service.*

Henrici's *Molds, Yeasts and Actinomycetes*—Revised by Charles E. Skinner, Ph.D., Chester W. Emmons, Ph.D., and Henry M. Tsuchiya, Ph.D. (2nd ed.). New York: Wiley, 1947. 409 pp. Price, \$5.00.

In the 17 years that have elapsed since the first edition of this book an enormous amount of work has been done, and a great deal of new information has been brought to light in the field of mycology, so that it is now a major subject in its own right. Consequently, on the basis of a rather concise monograph on molds, yeasts, and actinomycetes written primarily for bacteriologists, the revisers of Henrici's work have been able to build an excellent textbook of 409 pages. The size and form of the book are little changed.

The emphasis of the first edition was on mycology for bacteriologists, and this has been admirably maintained by the writers of the 2nd edition. Technical advances are described from a functional point of view and are incorporated in a much enlarged chapter III. The medical aspects of mycology have been enlarged because knowledge in that field has enlarged. On the other hand, industrial and other aspects have also been much expanded so that the treatment of the whole subject is well balanced.

In general, the 2nd edition presents more on the activities of yeasts, molds, etc., than did the first. The sexual phenomena of yeasts and molds have been more fully described, and new developments in the field of hybridization are discussed. New classifications are given (one adapted from Stelling-

Dekker replaces the old one for *Endomycetaceae*) and, in general, the whole book has been enlarged and changed where new developments have necessitated it, and large sections of obsolete material have been deleted. There is an extensive new chapter on variations; the chapters on fungus diseases are entirely revamped and enlarged; there are new chapters on biological activities, morphology and classification of yeasts and molds; new material on fermentations, spoilage and antibiotics; and much else of interest and value.

One appreciates the sympathetic attitude of the authors who, in suggesting certain mycological reference books for bacteriologists, warn that some are difficult. This bacteriologist finds such attitude throughout the book one of its most valuable features as it keeps the treatment on a fundamental and generalized level most helpful to those of us who are not, like the authors, experts in mycology. — MARTIN FROBISHER

Medical Education and the Changing Order—By Raymond B. Allen, New York: The Commonwealth Fund, 1946. 142 pp. Price, \$1.50.

Dr. Allen's monograph of the New York Academy of Medicine series on current trends in medical education, has the twin virtues of conciseness and easy readability. He brings to the subject the unusually broad academic background of a doctor of philosophy as well as a doctor of medicine, to which was added the graduate training of a surgical specialist. His years at Columbia, the New York Post Graduate, Wayne

University, and at the University of Illinois, have given him the experience to describe with authority and assurance the problems faced by the medical student, teacher, practising physician, and the patient. For both the health counsellor and patient, medical education is demonstrated to be a life-long process for which they have a joint responsibility.

While the emphasis in this volume is on today's widening horizons of opportunity presented to medical educators and physicians in the current changing social order, Dr. Allen supports his thesis with an illuminating historical account of how we have reached our present stage of development. In a society in the process of continuous dynamic change, the obvious task of education and of forms of health service is not only to adapt to meet new conditions, but to attempt to visualize them in advance. Dr. Allen points out that the organized profession has shown vigorous concern for the maintenance of high medical standards, but has failed "to exhibit sufficient social insight and aggressive leadership in moulding public opinion" in working out a more comprehensive plan for rendering medical care to the whole population.

If doctors are to be trained to provide such leadership, better educational foundations must be laid if the physicians of tomorrow are to be oriented to the full range of their anticipated fields of usefulness. The process must begin in the home and in primary school, for it has been amply demonstrated that most medical students made their decision as to career before entering high school. The function of the undergraduate college years is largely that of guidance.

Since the newer concept of medical study is to consider it to embrace the physical, psychological, and social factors bearing on health and disease, a

very much broader educational base must be constructed on which to build all through the school years and extending into the internship and residency. Dr. Allen develops very clearly the newer requirements of these years of formal study. Also, he brings out the burning and unsolved problem involved in the discovery and encouragement of good teachers of medicine. Actually, this issue has become even more acute in the short time since the publication of this monograph. Unwise policies during the war and lack of adequate economic reward are resulting in a serious scarcity of young medical men and women for teaching and research careers.

Dr. Allen's little book should provide informative and interesting reading material for nursing, social service, and other allied medical groups. If the team work job which the public expects of us is to be accomplished, it is essential that all workers are informed as to what each member of the team is doing.

J. A. CURRAN

Penicillin in Syphilis—By J. E. Moore, M.D. Springfield: Thomas, 1947. 319 pp. Price. \$5.00.

The book under report is well written and displays the clear and forceful style of the author. In the coverage of subject material it appears to be as complete as is to be expected from the state of knowledge prevailing at the time of writing. In common with all volumes devoted to a medical subject in the early stages of its development, the work risks becoming obsolete at any early date due to the rapid accumulation of data resulting from more exhaustive studies and more prolonged experience.

Many of the charts display the results produced by 300,000, 600,000, and 1,200,000 units of penicillin given over the period of one week. The schedules involving these amounts have been largely abandoned and the findings

should not be confused with the character of results which apparently may be produced by a more generous use of the antibiotic. Also, the superior value of therapies employing penicillin and arsenic as compared to penicillin alone is not being confirmed by recent analyses.

The author is wisely conservative in the matter of the value of penicillin therapy in cardiovascular and neurosyphilis because of the prolonged post-treatment observation periods which are required for an evaluation, and in the matter of differentiating reinfection and relapse, another phase of the work which cannot be resolved on the basis of presently available knowledge.

The "cumulative failure rate" is a statistical procedure which may be induced to reveal different values through the expedient of varying the time intervals which are involved in the computation. In the opinion of the reviewer, the "cumulative re-treatment rate" would seem to be more appropriate as the rate includes patients re-treated for all reasons.

JOHN F. MAHONEY

Practical Nursing—An Analysis of the Practical Nurse Occupation with Suggestions for the Organization of Training Programs. Washington: Federal Security Agency, U. S. Office of Education, 1947. 144 pp. Price, \$.55.

This *Bulletin* is notable in that it is the first effort ever made to analyze the occupation of practical nursing, and timely in that it appears at a time when the acute nursing shortage is focusing attention on the preparation and use of the practical nurse.

It gives a clear and comprehensive definition of the field as distinguished from that of professional nursing, an analysis in table form, covering 119 pages, of what the practical nurse must be able to do, what she must use and what she must know, as well as concrete suggestions for training programs.

It should prove useful to communities that are planning new schools and also to already existing schools as a criterion for evaluating their programs.

The names of the persons who were on the working committee which produced the *Bulletin* and the well known organizations which they represent lend authority to this publication.

ETTA A. CREECH

Standard Methods for the Examination of Water and Sewage—By American Public Health Association and American Water Works Association. (9th ed.) New York: American Public Health Association, 1946. 286 pp. Price, \$4.00.

The material in the ninth edition of this standard laboratory manual for the physical, chemical, and biological analyses of water and sewage is placed in a more convenient form than any previous edition. The number of major parts have been reduced to four, related analyses are rationally grouped, confusing Roman numerals have been eliminated, and references to previous or subsequent procedures are paginated. These improvements will promote speed in use.

The principle changes are in the tests of water for odor, hardness, pH, carbon dioxide, alkalinity, arsenic, iron, chromium, magnesium, potassium, fluorides, phosphates, cyanide, tannin and lignin, residual chlorine, hydrogen sulfide, and methane. In the main the new procedures require greater analytical skill, and often call for reagents that the average laboratory will not have readily at hand. For making colorimetric determinations of iron, potassium, silica, copper, aluminum, chromium and magnesium, use of an optical or photoelectric colorimeter, or a spectrophotometer is recommended. For pH determinations, a pH electrometer is recommended. Although alternative methods will continue in use, the wider

use of instrumental methods in water analysis may be expected. A helpful feature is a brief statement of the chemical basis of the test given before each analytical procedure for water. The section on residual chlorine tests is outstandingly excellent.

There are modifications and additions to procedures on dissolved oxygen and grease and sludge tests. The use of tryptone glucose extract agar for bacterial plate counts is permitted, and lauryl sulfate tryptose broth is listed. The bacteriological control of swimming and bathing water is included among the standard methods for bacteriological examination of water, removing that topic from its provisional status in the eighth edition. EMIL T. CHANLETT

Sewerage and Sewage Treatment
—By *Harold E. Babbitt*. (6th ed.).
New York: Wiley, 1947. 692 pp.
Price, \$6.50.

The last edition of this textbook was published in 1940. During the war municipal sewerage works and treatment plants construction practically stopped, but many military installations were built. Information obtained from military establishments has been included. In comparison with former editions, the book stresses more the problems of design, methods of treatment, and operation of plants than construction. Data in the book have been brought up to date, the discussion of the rational method of determining runoff has been revised, a chapter on hydraulics has been improved, high rate filters, contact aerators and other newer developments have been added.

Practically all problems given in the appendix have been changed and many new problems have been added. Of particular interest is the extensive increase in references to current literature, numbering some 527, which increases the value of the textbook materially for advanced students and those

in the field who need more detailed information than a textbook ordinarily can supply. The book is printed in clear type on good paper.

WILLEM RUDOLFS

Health and Fitness—By *Florence L. Meredith*. Boston: Heath, 1947. 325 pp. Price, \$2.20.

Concentrating on the essentials for those students who wish to be able to do the things that bring pleasure, usefulness, and social acceptance, the author relates good health practices with knowledge presented through modern text, impressive illustrations, and timely examples. The numerous and varied study guides will help good teachers who naturally create heavy workloads for themselves. The vocabulary is appropriate for literate students who are at ease with clear expression.

This text will be most useful in imaginative educational systems. The memorizing of definitions, lists of characteristics and enumerated functions cannot be the basis for evaluations in a course using it. Its presentation is consistent with the author's assumption that the student is seeking knowledge about himself as a means of achieving satisfactions resulting from good health. The teacher, then, must evaluate student comprehension through discussion and ability to deal with problems, preferably actual health problems in clinical practice, laboratory demonstrations, and community public health programs. Consequently, the assumption of student literacy, ability, and interest must be matched by imagination, information, and initiative on the part of the teacher.

Having provided a wide variety of subject matter, the author places on the student much of the responsibility for profiting from this text. A non-medical reviewer of this book was impressed by the wealth of useful scientific information of interest to high school students.

The book evidences professional com-

petence readily appreciated by good students. It also provides an opportunity for exposure to the influence of a good mind. Alert students with professional possibilities and vocational ambitions will respond to it. Quite complete subject coverage is achieved through the variety of activities, age levels, and types of persons described. Students will find themselves personally involved in most chapters.

JOHN KHANLIAN

Old People—Report of a Survey Committee on the Problems of Aging and the Care of Old People—
Chairman, B. Seeborn Rowntree. New York: Oxford University Press, 1947. 202 pp. Price, \$1.50.

This report gives the present status of social action in regard to the "care and the comfort of the aged poor" in the surveyed areas, and contains recommendations directed particularly to authorities of public and voluntary agencies.

The National Insurance Act of 1946 and the "projected" National Health Service give England stronger social legislation than we have. When the first of these two Acts comes into full operation, admission to an institution will not be a disqualification for drawing a retirement pension. Two viewpoints regarding the care of the aged, chronically ill are given.

The committee consider that the statutory inspection of all voluntary homes is desirable, but they have been unable to find a definition of a "voluntary home" that would make inspection administratively possible.

Certain concrete recommendations regarding the nature of research projects are made.

By and large, the aged in England

present and have the same problems as do our old people.

This report will be of interest to all persons who are concerned with the comfort and welfare of aged individuals. With only a few changes, this committee report would be applicable to the most populous communities in this country.

JOSEPH H. KINNAMAN

The Relation of Diseases in the Lower Animals to Human Welfare
—By William A. Hagan, et al. New York: New York Academy of Sciences, 1947. pp. 351-576.

This series of papers was presented at a conference held by the Section of Biology of the New York Academy of Sciences in March, 1946. Contents include papers on Rabies by Harald N. Johnson; Equine Encephalomyelitis by Raymond A. Kelser; Psittacosis, Ornithosis, and Related Viruses by Herold R. Cox; Brucellosis by I. Forest Huddleson; The Prevention of Plague by Karl F. Meyer; Animal Tuberculosis by William H. Feldman; Anthrax by C. D. Stein; *Erysipelothrix rhusiopathiae* Infection in Swine and in Human Beings by Joseph V. Klauder; and Animal Parasites Transmissible to Man by Willard H. Wright.

Besides the scientific contributions there is a tabulation of estimated cost of various livestock diseases in a recent year which is said to exceed \$400,000,000 in the United States, with the probability that it approaches a billion dollars. Emphasis is placed on freedom in the United States from such diseases as rinderpest, foot and mouth disease, fowl pest, bovine piroplasmiasis and contagious pleuropneumonia. This is a reference volume of importance which should be available in all libraries.

REGINALD M. ATWATER

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Ten Experts Say—German measles and mumps provide the strongest argument in favor of childhood exposure to certain communicable diseases. Rather than attempt to prevent the spread, physicians should encourage exposure of healthy children to chickenpox, measles, and the two infections mentioned above, this group of pediatricians advise. This does not apply to sick or debilitated children, of course, or those under 3 years old. Triple vaccines are discussed pro and con.

ANON. Pediatrics. New England J. Med. 236, 23-867 (June 5), 1947.

Health Problem in 26 States—If there is any reader of our *Journal* who does not know the essential story of rabies in man and animals he will find all he needs in this brief review article.

CHANT, H. L. Rabies. Am. J. Nurs. 47, 6 390 (June), 1947

Bearing Babies without Pain—You've heard no doubt about the English doctor who talks his maternity patients into wanting "natural" childbirth without benefit of drugs. Well, here his method is described, inch-by-inch.

COTTEN, H. Childbirth Without Fear. Am J Nurs. 47, 6-392 (June), 1947

Fourth Year of High Incidence—Not only does this paper tell where, in the U.S.A. the 25,000 polio cases of the 1946 epidemic were located, but it relates the conditions in other parts of the western hemisphere. Briefly it considers methods of spread. Recent epidemiologic data strengthen, rather than weaken, the person-to-person contact theory, says the author.

DAVIS, C. C. Incidence of Poliomyelitis in

1946. Pub. Health Rep. 62, 25:901 (June 20), 1947.

Darkening Forecasts—You may think a paper on the threatening "recession" is not public health literature, but I do. If the storm hits us, it will affect public health generally and your little job too. You'll find a lot to mull over in this well documented whither-are-we-drifting analysis.

GILLMOR, D. S. Are We in for a Depression? Survey Graphic. 36, 6:325 (June), 1947.

From Human Volunteers—We've learned that infectious hepatitis is a virus disease spread through the intestinal-oral route and can be prevented by passive immunization. Evidence is presented that it may run its course without the appearance of clinical jaundice. If you are satisfied with these few dry bones picked from the findings, then you aren't much interested in this relatively new addition to our growing list of public enemies.

HAVINS, W. P. The Etiology of Infectious Hepatitis (and) MALLORY, T. B. The Pathology of Epidemic Hepatitis. J.A.M.A. 134, 8 653 (June 21), 1947.

Structure of the Endospore—Although you may have the merest smattering of bacteriology you'll be thrilled with these electron microphotographs of bacteria popping out of germinating spores and a picture of a bacillus with what looks like warts.

KNAYSER, G, et al. A Study, with High-Voltage Electron Microscope, of the Endospore and Life Cycle of *Bacillus Mycoides*. J Bact. 53, 5:525 (May), 1947.

Teamwork Does It—Now that the tumult and shouting have died away,

you may read in peace the last words in the care of poliomyelitis patients from the medical, psychological, and nursing angles.

LOWMAN, C. LER, *et al.* Poliomyelitis. *Am J Nurs* 47, 6:367 (June), 1947.

Inconclusive—DDT was applied to 4-square-mile areas in 2 cities threatened by poliomyelitis. A temporary reduction of flies was achieved. Though the demonstrations taught us a lot about the difficulties and costs of wholesale fly abatement, they did not offer evidence of its value in the control of polio.

MELNICK, J. L. Fly-Abatement Studies in Urban Poliomyelitis Epidemics During 1945. *Pub Health Rep.* 62, 25:910 (June 20), 1947.

Price of Neglect—When virulent smallpox hit an unprepared city, the mass vaccination program almost overwhelmed the medical and health fraternity.

PALMQUIST, E. E. The 1946 Smallpox Experience in Seattle. *Canad. Pub. Health J.* 38, 5:213 (May), 1947.

As the World Shrinks—Now epidemic in war-stricken areas, tuberculosis seems on the way out in lucky U.S.A. But until every country is free, no country can be entirely safe—to paraphrase a potent slogan.

PARRAN, T. The Control of Tuberculosis in the Americas. *Pub. Health Rep* 62, 23:827 (June 6), 1947.

Changing Food Habits—When women make up their own minds to adopt desirable nutritional practices, they are much more likely to improve food habits permanently than if they were merely

influenced by lectures. Both in increasing family consumption of milk and in securing coöperation in infant feeding, the group decision method proved superior.

RADKE, M., and KLISURICH, D. Experiments in Changing Food Habits. *J. Am. Dietet. A.* 23, 5:403 (May), 1947.

The Last of the Louse—Here are all the details—with how-to-do-it photographs—of the now famous Naples typhus fever epidemic which mass delousing nipped at the start.

SOPER, F. L., *et al.* Typhus Fever in Italy 1943-1945 and Its Control with Louse Powder. *Am. J. Hyg.* 45, 3:305 (May), 1947.

Now at the 102nd Meridian—Field surveys, covering half the country, record the eastward creep of plague via rodents and their fleas. The possibilities of introduction into more remote municipal areas by migrations or through commerce deserve continuous and expectant attention, says this student of the problem.

WAYSON, N. E. Plague—Field Surveys in Western United States During Ten Years (1936-1945). *Pub Health Rep* 62, 22:780 (May 30), 1947.

Histoplasma Capsulatum—Has the word histoplasminosis crept into your vocabulary while you still have only fuzzy ideas about the public health implications of this novelty? Then you had better master this paper, though it is mostly medical speculation. Coccidioidomycosis adds to the confusion.

ZWERLING, H. B., and PALMER, C. E. Pulmonary Calcification in Relation to Sensitivity to Histoplasmin. *JAMA.* 134, 8:691 (June 21), 1947.

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

- THE AMERICAN YEAR BOOK—1947. Edited by William M. Schuyler. New York: Thomas Nelson, 1947. 1110 pp. Price, \$12.00.
- AN APPROACH TO SOCIAL MEDICINE. By John D. Kershaw, M.D., Baltimore: Williams & Wilkins, 1946. 329 pp. Price, \$4.50.
- ATLAS OF CARDIOVASCULAR DISEASES. By Irving J. Treiger, M.D., St. Louis: Mosby, 1947. 180 pp. 244 ill. Price, \$10.00.

ASSOCIATION NEWS

A.P.H.A. PRESENTS TESTIMONY ON NATIONAL HEALTH ACT OF 1947

On June 27, Reginald M. Atwater, M.D., Executive Secretary of the American Public Health Association, appeared as a representative of the Executive Board of the Association before the Subcommittee on Health of the Senate Committee on Labor and Public Welfare in the U. S. Senate, Washington, D. C., to present testimony as approved by the Executive Board on Senate Bill 545, the National Health Act of 1947.

A brief digest of the testimony is appended. Readers of the *American Journal of Public Health* desiring the full testimony can obtain a copy by request from the Association, 1790 Broadway, New York 19, N. Y.

The public health professions are deeply concerned with Senate Bill 545 which relates to the medical care available to the American people and which is also intimately concerned with the organization of the health services of the federal government. It was pointed out that the official statement of the Association policy, "Medical Care in a National Health Program," adopted at the 1944 Annual Meeting, recognizes that a large portion of the population receives insufficient and inadequate medical care, chiefly because persons are unable to pay the cost of services on an individual payment basis when they are needed, or because the services are not available.

The testimony documents present inadequacies of medical care and points out that many Americans find it difficult to carry the rise in costs. It was concluded that a majority of the population does not receive adequate medical

care and that these costs are decidedly uneven and unpredictable.

In the opinion of the Association, Senate Bill 545 does not meet the Association's criterion of a national program for medical care, being designed primarily to provide federal aid to the states for the medical and dental care of the needy. It is implicit in the Bill that there must be application of a means test to determine those whose incomes are sufficiently low to be eligible. In actual practice it is believed that only recipients of public assistance and those who are one step removed from this state could receive benefits under this Bill. It was further pointed out that the size of the federal appropriation is such as to represent the cost of care for only about 5 per cent of the population, to say nothing of the curtailment of these funds by the expensive as well as cumbersome administrative machinery which would be necessary to administer the means test.

Realizing that Congress may not be prepared at the moment to legislate a complete program, it was suggested that programs to satisfy some of the most urgent health needs be given priority, a procedure similar to that adopted by Congress last year, when it passed the Hospital Survey and Construction Act. Reference was made to the necessity for the expansion of comprehensive preventive services to the entire population of the United States. The fact that 3,000 mothers die needlessly as a result of childbirth and that about 31,000 babies who could have been saved die in their first year demands further support of

maternal and child health services. Funds are urgently needed as well for cancer, heart disease, and diabetes. An especially urgent need relates to medical education and research. Only recently the presidents of 19 American universities joined in a warning of the uncertain future of medical education upon which medical care and public health are dependent. They declared that with present resources few if any of the 70 recognized medical schools of the United States could be confident of maintaining their programs at a high level in the future. Therefore, federal grants-in-aid for medical education and research are needed and may play an important rôle in increasing our scientific knowledge of the prevention, control, and treatment of those diseases before which we are powerless today. It was further suggested that Congress consider strengthening the Hospital Construction program by improving the formula for allocation of federal funds and providing funds for operation and maintenance in the areas of greatest need.

The American Public Health Association is already on record as favoring the establishment of a Cabinet Department of Health, Education and Security by converting the Federal Security Agency into such a department. The creation of a national health agency as an independent agency without Cabinet status as provided in S. 545 is disapproved.

An important oversight is that the Director of the Office of Medical and Hospital Care Services is required by the Bill only to have at least five years of active medical practice and to be "outstanding in the field of medicine." It was pointed out that such experience is seriously inadequate because these positions require years of training and experience in medical and public health administration, subjects not taught in medical schools and rarely included in the experience of private practitioners.

Important also is the fact that although the stated purposes of S. 545 include the phrase "to expand the activities of the Public Health Service," the organizational scheme which is outlined actually reduces the Public Health Service to a subordinate position as one of seven or more constituent units. This might result in the health services of the federal government being administered by a physician unqualified in public health and administration, who might have a position of authority over such highly qualified medical and public health administrators as the Surgeon General of the Public Health Service.

The Association went on record as believing it important to link up preventive and curative medicine, and was of the opinion that the proposed set-up of S. 545 is undesirable. It was believed that the public interest was not properly represented on the national medical care council provided in the Bill, since only three of the nine members represent consumer interest, while five of the nine, an absolute majority, are physicians. It was the opinion of the Association that the power of a national medical care council to overrule the decisions of the director with regard to approval of state plans or modification thereof is contrary to sound administrative practice.

Senate Bill 545 fails to make any provisions for federal or state standards with regard to methods of administration or quality of care. The failure to include such a requirement would permit inefficient administration of the programs by unqualified personnel. The Bill explicitly prevents federal standards of any sort. The Association stated that it was manifest that federal standards have played an important rôle in developing high quality health services at the state and local level.

One feature of the Bill was strongly approved, namely, the plans to establish

a national institute of dental research, but it was believed that the ceiling of a \$600,000 appropriation was too low.

In conclusion, the Association does not consider S. 545 to represent an adequate national health program. Alternative programs have been suggested, such as the expansion of comprehensive public health services both in scope and content, federal aid to medical education and research, and liberalization of federal grants to provide hospital facilities. The proposed reorganization of the federal health services in S. 545 is believed to be administratively unsound. The in-

adequate requirements for the administrators of the medical and dental care programs, the lack of sufficient consumer representation on advisory boards, the power given to national advisory councils to overrule decisions of responsible administrators, the failure to require state plans to set minimum standards of administration and services, and specific prohibition of all federal standards lead to the conclusion that Senate Bill 545 does not sufficiently protect the public interest in the expenditure of public funds for medical care.

APPLICATION FOR HOTEL ACCOMMODATIONS

American Public Health Association, October 6-10, 1947

NOTE: Single rooms are very limited in number. Please arrange to occupy twin-bedded rooms.

HOUSING BUREAU, 16 Central Pier, Atlantic City, N. J.

Please reserve the following:

Hotel	First Choice	Hotel	Fourth Choice
Hotel	Second Choice	Hotel	Fifth Choice
Hotel	Third Choice	Hotel	Sixth Choice

Room(s) with bath for person(s). Rate \$ to \$ per room.

Arriving Atlantic City A.M. Leaving P.M.

NOTE: You will receive confirmation direct from the hotel accepting the reservation when made.

Rooms will be occupied by:

Name	Street Address	City	State

WESTERN PUBLIC HEALTH MEETINGS — 1947 MODEL

There was repeated in 1947 a pattern of consecutive state and regional meetings in Western states comparable to that of 1943, 1944, and 1945. Participating in all the meetings was a team organized by the American Public Health Association and made available to the states for their programs. The team members this year consisted of Dr. Mary Crosse, Deputy Senior Assistant Medical Officer of Health (for Maternity and Child Welfare), Birmingham, England; Walter J. Pelton, D.D.S., consultant public health dentist on the staff of the U. S. Public Health Service; James H. Steele, D.V.M., Chief Public Health Veterinarian, U. S. Public Health Service; Eleanor Palmquist, R.N., and Dorothy Rusby, R.N., both Assistant Directors, National Organization for Public Health Nursing; Carl E. Buck, Dr. P. H., Field Director, A.P.H.A.; Francis B. Elder, Engineering Associate, A.P.H.A., William T. Ingram, Engineering Field Associate, A.P.H.A.; Allan Twichell, Technical Secretary, A.P.H.A. Committee on the Hygiene of Housing; Charles B. Frasher, technical consultant in personnel administration, A.P.H.A. Merit System Unit; and Reginald M. Atwater, M.D., Executive Secretary, A.P.H.A.

Beginning with the meeting of the Missouri Public Health Association in Jefferson City the first week of May, the circuit moved on to Minneapolis, where a group of agencies including the State Department of Health, the University of Minnesota School of Public Health, University Continuation Center, and a new organization of public health workers in Minnesota actively participated. At the same time as the Missouri meeting a meeting of the North Dakota Public Health Association was held in Fargo attended by part of the

team, reviewing plans and prospects in that state. This was followed by a one day meeting in Omaha, Neb., at which consideration was given to the wisdom of forming a state-wide organization of public health workers. Special emphasis was placed on the development of full-time city-county health units according to the plan of the State Department of Health.

The fifth meeting of the series was held in Colorado Springs under the auspices of the Colorado Public Health Association. The event of this meeting was the presence of Dr. Florence Sabin of Denver, recently featured through popular magazines for her state-wide activity in the promotion of full-time health service and in the reconstruction of Colorado's public health.

Excellent meetings of the New Mexico Public Health Association and of the Arizona Public Health Association were held respectively in Albuquerque and Tucson. The attendance of these meetings when compared with the number of full-time public health workers in these states was extraordinary, since practically every person physically able to be present was on hand.

The Northern California Public Health Association held a meeting in conjunction with the meeting of the Western Branch of the American Public Health Association in San Francisco the week of May 25. The feature of the program of the Northern California Public Health Association was the address by Dr. Mary Crosse on the care of premature babies in England.

The meeting of the Western Branch brought out more than 800 persons from eleven Western states, several of the Provinces of Canada, Alaska, Hawaii, and the Philippines. An excellent program included addresses by

the Surgeon General of the U. S. Public Health Service, Dr. Thomas Parran, by Dr. Florence Sabin, and other national leaders, but the principal part of the program was contributed by those members of the Western Branch who spoke of programs specially adapted to the Western area and operated in spite of serious difficulty growing out of sparse populations and economic conditions. This meeting was under the Presidency of Karl F. Meyer, Ph.D., who has served during the war years. His successor as President of the Branch is Dr. Florence Sabin, of Denver, recognized as one of the most dynamic leaders in the West at the present time.

The new officers of the Western Branch are:

President—Florence R. Sabin, M.D., Denver, Colo.

President-Elect—George M. Uhl, M.D., Los Angeles, Calif.

Vice-President—Mrs. Sadie Orr Dunbar, Portland, Ore.

Vice-President—Lawrence J. Peterson, Boise, Ida

Secretary—Walter S. Mangold, Berkeley, Calif.

Treasurer—Guy S. Millberry, D.D.S., Los Gatos, Calif.

Subsequent stops were made in Boise for the Idaho Public Health Association, and in Salt Lake City for the Utah Public Health Association where meetings were held in which large numbers participated, including a good many citizens concerned with public health as a social force.

Altogether eleven meetings were held

in this circuit, attended by 2500 persons, a large majority of whom would have found it difficult to attend a national meeting even if it had been held in the territory of the Western Branch. There were many expressions of appreciation for the opportunity to hear competent new speakers and especially to share the British experience as brought out by Dr. Crosse.

Inquiries already have reached the central office with reference to the possibility of a similar team of speakers being organized for a circuit in 1948. The Executive Board has indicated that if such a team is desired and is organized, first priority for the services of the Association team should be offered to states in the territory of the Southern Branch and other parts of the United States where consecutive meetings can be arranged. It is apparent that the Western states again will orient a good many of their state meetings to the meeting of the Western Branch which will be held in Salt Lake City, Utah, the last week of May, 1948. Persons interested in a possible circuit for 1948 should communicate with Dr. Atwater at the A.P.H.A. office.

Appreciation of the American Public Health Association has been extended to the National Organization for Public Health Nursing, the United States Public Health Service, the British Information Services, and other agencies which have coöperated in making the circuit possible, and which have provided the services and travel expense of their representatives.

THE 1947 EVALUATION PROJECT

During the past twelve weeks, calculating machines and typewriters have hummed steadily in the offices of the Committee on Administrative Practice checking the figures, the additions, and the rates in an effort to give a grade of

GOOD on every single item on 127 Evaluation Schedules received for grading and analysis in the 1947 Evaluation Project.

These schedules were sent in by local health departments in 22 states, the

Territory of Hawaii, and the Provinces of Manitoba, Ontario, and Quebec. Despite shortages of personnel, mass vaccination programs, and other factors which prevented some units from carrying the evaluation project through to completion, participation in 1947 increased 25 per cent over last year.

State Participation—State programs, using the evaluation process for improving and extending local public health units, have been inaugurated in Illinois, Kansas, Michigan, Mississippi, New York, and Texas. Since 1942 when this phase of the program was initiated by the Association, Michigan and Texas have accelerated their activity each year, and a large proportion of the 1947 schedules came from those two states—44 from Michigan and 33 from Texas. Under the plan operating in those states, technical field staffs are trained in the use of the *Schedule* in order to stimulate full-time health departments to use it effectively. Standardized record systems are being developed. Grading has been undertaken and the results are then compared with the Association grading. The information thus obtained has been used for program planning, for health education, for more equitable allocation of funds, for inservice training, and in many other ways.

Local Participation—Many of the participating units have chosen to submit schedules annually during the past five years or longer. Comparison of the 1947 grading with that for a previous year, in almost every instance, showed decided improvement in the programs. On the schedules the itemization of problems and plans was more carefully thought out than in former years.

Definite evidence of improvement in services stimulated through the use of the Evaluation Process is shown in the following extracts from 1947 schedules: From a Midwest city: "One year ago our *Evaluation* showed that 30 per cent of the cases of active tuberculosis were

at home because they refused hospitalization or left against medical advice. As a means of solving this problem, a medical social worker was secured. This worker has acted as consultant to Health Department nurses and sanatorium superintendent, and has provided direct social service to patients at home, in hospital, and clinic. Now only 15 per cent of active cases are at home, and while 43 per cent of sanatorium discharges were against advice during the year, only 3 per cent left against advice from August 1 to December 15. The social worker is considered to be worth while and will be continued."

From a Southern city: "Attention was focused on the high death rate from diarrhea and enteritis on the 1945 *Evaluation Schedule*. The Health Officer held conferences with pediatricians, reviewed the deaths, and evolved plans for special emphasis on this type of illness. Special instructions were given visiting nurses on care and feeding of small children. There was not a single death from this cause in 1946."

Health Practice Indices—Data submitted on schedules from some 300 health departments for the years 1943, 1944, 1945, and 1946 will appear in chart form in the new edition of *Health Practice Indices* now in preparation. The inclusion of data for four years will give a wider spread of units reporting. Although its uses are many for health education purposes, not the least important is to convince governing bodies of the need for increased appropriations. It is less difficult to arouse an interest when citizens can be shown exactly where their community stands among 300 others. If it is high on the chart they want to keep it that way and if it is way down at the bottom, they want to know why.

The Evaluation Schedule—In order to keep the *Schedule* up-to-date with prevailing public health practices, it is necessary to revise it periodically. A

Committee on Revisions has been working on a new schedule for months, which will be ready in time for reporting 1947 activities. At present it is being tried out in various parts of the country and, from all reports, health department staffs, not only the health officers but the clerks and typists, find it a vast improvement over the last form. They say it is easier for a beginner to understand. They are also pleased to find that it does not demand excessive record changing. A *Guide* to the use of the new schedule has also been prepared

and it will have a chapter on sampling methods which will make it easier to get information.

Institutes—Another regional institute on the Evaluation Process is planned, and will probably be held on the West Coast. It will follow the pattern of those held at the University of Michigan and North Carolina.

The Committee on Administrative Practice will welcome letters telling of uses that have been made of the evaluation material, as well as comments on the new publications.

Nominations for the Governing Council

In accordance with the By-laws of the Association, the Nominating Committee for Governing Council Members consisting of one Fellow elected by each Section and a Chairman appointed by the Executive Board, reports the following nominations for the Governing Council. The Chairman of the Committee is Earle G. Brown, M.D., Nassau County Commissioner of Health, Mineola, N. Y. The other members are: Frank C. Cady, D.D.S., Dental Health Section; Marietta Eichelberger, Ph.D., Food and Nutrition Section; Alexander G. Gilliam, M.D., Epidemiology Section; Arthur E. Gorman, Engineering Section; Lloyd M. Graves, M.D., Health Officers Section; Myrtle Greenfield, Laboratory Section; Howard W. Lundy, Dr. P. H., Public Health Education Section; Pearl McIver, R.N., Public Health Nursing Section; Hugo Muench, M.D., Vital Statistics Section; C. O. Sappington, M.D., Industrial Hygiene Section; John M. Saunders, M.D., Maternal and Child Health Section; David Van der Slice, M.D., School Health Section.

The By-laws provide that "upon the petition of twenty-five Fellows, the

Nominating Committee shall add the name of any Fellow to the nominees selected by it, provided such petition is received not less than fifteen days before the Annual Meeting."

The terms of ten elective councilors will expire at the time of the Atlantic City Annual Meeting. The ten nominees receiving the highest number of votes on a written ballot cast by the Fellows present and voting at the Annual Meeting will be elected to fill the three year term expiring in 1950.

SURVEY OF STATISTICAL PERSONNEL AND ACTIVITY

A survey of statistical activity and statistical personnel in public health agencies is currently being conducted under the joint auspices of the A.P.H.A. Vital Statistics Section and the U. S. Public Health Service. Questionnaires are being submitted to the chief executives and individual statistical workers in the state and the large city health departments. Valuable information on the following topics is being anticipated when the survey is completed:

1. Salary levels in the various classifications.
2. Factors which have motivated the men and women now engaged in public health

statistics to seek these careers. This piece of information should throw light on the methods which might be used in the recruitment of statisticians.

3. Qualifications and duties of personnel now employed in statistical work in public health agencies. This information should prove important background material for the revision of the report on Educational Qualifications of Public Health Statisticians which is now under revision.

4. Need for in-service and other training programs.

5. Need for reorganization of statistical activities.

6. Degree of the prevailing personnel shortage and its effect on the quality and areas of service given.

It is hoped that a preliminary analysis

of the data will be ready to be presented at the Annual Meeting at Atlantic City.

DR. HOWARD M. KLINE RETURNS TO
A.P.H.A. STAFF FROM LEAVE

Howard M. Kline, Ph.D., Bethesda, Md., who has served for the last year as Technical Secretary of the Subcommittee on Medical Care of the American Public Health Association, has returned to the staff of the Subcommittee after several months of service as a staff member of the President's Scientific Research Board of Washington. This Board was created by executive order

for the purpose of inventorying all research activities in the United States, with special reference to the research being conducted within the federal establishment and that which is being conducted outside with federal funds. Dr. Kline directed the survey of medical research and conducted special studies incident thereto.

During Dr. Kline's leave the staff of the Subcommittee on Medical Care was guided by Milton Terris, M.D., M.P.H., Medical Associate of the Subcommittee, which is under the Chairmanship of Joseph W. Mountin, M.D.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Edward W. R. Best, M.D., D.P.H., North Okanagan Health Unit, Vernon, B.C., Canada, Director
John R. Bourne, M.D., Box 186, Roosevelt, Utah, City Physician
Thelma C. Buckthorpe, A.B., Box 538, Waynesville, Mo., Acting Health Officer, Pulaski Health Unit
Wilfred D. David, M.D., 7 Prairie Ave., Newport, R. I., Senior Asst. Surgeon (R), U. S. Public Health Service
William P. Doherty, V.M.D., 135 Broad St., Bridgeton, N. J., Health Officer
Milton Feig, M.D., M.P.H., 185 Thompson Shore Rd., Manhasset, N. Y., Fellow U. S. Public Health Service; with Nassau County Health Dept.
Morris Fiterman, M.D., M.P.H., 6152 Spruce St., Philadelphia 39, Pa., Medical Inspector, Philadelphia Health Bureau
Kenneth W. Haworth, M.D., M.P.H., 805 Sixth St., Eureka, Calif., Director, Humboldt County Health Dept.
Samuel L. Henke, M.D., 314 Grand Ave. E., Eau Claire, Wis., Member, State Board of Health
Michael Lipari, M.D., M.P.H., 34 South St., Middletown, N. Y., Asst. District Health Officer, State Dept. of Health
Irvin D. Litz, M.D., 218 E. First St., Long Beach 7, Calif., Asst. Health Officer
Otto Lohman, M.D., 160 Barnard Rd., Manteno, Ill., Health Officer, Manteno State Hospital

Harold C. Miles, M.D., M.P.H., 602 Washington St., Olean, N. Y., Asst. Commissioner, Cattaraugus County Dept. of Health
W. O. B. Nelson, M.D., Fergus Falls, Minn., Health Officer
Forrester Raine, M.D., 425 E. Wisconsin Ave., Milwaukee, Wis., Member, State Board of Health
Harold E. Smith, M.D., Middlefield, Conn., Health Officer
Robert L. Smith, M.D., 513 N. Rampart St., New Orleans 16, La., Director, Bureau of Tuberculosis Control, City Health Dept.

 Enrique Marrero y Vela, D.V.M., Laboratorio Om, Ayestaran 196, Havana, Cuba, Bacteriologist
 Mary J. McClintock, B.S., Rt. 8, Box 440, Oklahoma City 9, Okla., Bacteriologist, State Dept. of Health
 Dr. Ludlow R. Stevens, 4712 Leiper St., Apt. E-2, Philadelphia 24, Pa., Research Work in Hematology and Bacteriology
 Morris R. Shub, B.S., 3905 Eldorado Ave., Baltimore 15, Md., Bacteriologist, Strassburger & Siegel
 Stanley Villafranca, M.S., Sanatorio "Carlos Duran," Cartago, Costa Rica, C.A., Head of Laboratory

Vital Statistics Section

Campbell R. Graf, B.A., 2305 Neil Ave., Columbus 1, Ohio, Statistician, State Dept. of Health
 E. C. Jenkins, City Hall, St. Joseph, Mo., Clerk, Board of Health
 Goldy D. Kleinman, A.M., 2407 Ocean Front, Santa Monica, Calif., Junior Public Health Analyst, State Dept. of Public Health
 B. Aubrey Schneider, Sc.D., American Cancer Soc., 47 Beaver St., New York 4, N. Y., Asst. Director, Dept. of Statistics and Special Services
 Clarence A. Burlage, 1437 Xanthia, Denver 7, Colo., Milk Sanitarian, City Health Dept.
 Emory J. Cook, Lakemont Dr., Augusta, Ga., Sanitarian, Richmond County Dept. of Health
 Rolf Eliassen, Sc.D., New York Univ., University Heights, New York 53, N. Y., Professor of Sanitary Engineering, College of Engineering
 John R. Fleming, B.A., Van Buren County Health Dept., Paw Paw, Mich., Sanitarian
 Francis R. Girard, State Dept. of Public Health, Fernald Hall, Amherst, Mass., Sanitary Technician
 Warren P. S. Hall, D.V.M., M.A., 9 Ontario St., Toledo 12, Ohio, Supt. of Food and Sanitation, City Health Dept.
 Robert M. Kennedy, A.B., 604 Mission St., San Francisco 5, Calif., Assoc. Engineer, Engineering Office of Clyde C. Kennedy
 Hoyt R. Mason, 70 Fisher Rd., Rochester 11, N. Y., Assistant Sanitary Inspector, Monroe County Dept. of Sanitation
 R. Kay Matthews, City Hall, Hugo, Okla.,

Sanitarian, Choctaw-McCurtain County Health Dept.

Robert L. Prichard, C.E., 5229 Greenwood Ave., Chicago, Ill., Sanitary Engineer (R), U. S. Public Health Service
 Rodrigo Puente, C.E., 105 Tejadillo, Cartagena, Colombia, S.A., Sanitary Engineering Student, Univ. of North Carolina
 Walter M. Scott, 3155 W. 40th Ave., Denver, Colo., Chief Health Inspector, City Health Dept.
 Henry B. Starr, Jr., 701 Persons Bldg., Macon, Ga., Public Health Sanitarian, State Dept. of Public Health
 Fred W. Thomas, C.E., Tennessee Valley Authority, Wilson Dam, Ala., Senior Sanitary Engineer
 Williams L. Timmons, 1215 H. St., Eureka, Calif., Sanitarian, Humboldt County Health Dept.
 C. William Tresslar, 114 Greenwood St., La-Habra, Calif., Sanitarian, Orange County Health Dept.
 Frank L. Woodward, B.E., 5821 Elliot Ave., S., Minneapolis 7, Minn., Director, Division of General Sanitation, State Dept. of Health

Industrial Hygiene Section

Edward R. Hawkins, M.D., 472 Union Ave., Elizabeth 3, N. J., Asst. Plant Physician, Standard Oil Co. of New Jersey
 Gordon W. Petersen, M.D., Supt., Medical Labs., Kimberly Clark Corp., Neenah, Wis.
 Ada Chree Reid, M.D., 1 Madison Ave., New York, N. Y., Physician in Charge, Tuberculosis Control Program, Metropolitan Life Insurance Co.
 Herbert E. Tomlinson, M.D., 905 Smith Tower, Seattle, Wash., Industrial Medical Consultant, State Dept. of Health

Food and Nutrition Section

Virginia L. Daly, B.S., R.D. 2, Box 627, Clayton 5, Mo., Staff Member, Dairy Council of St. Louis
 Doris P. Longman, M.S., 175 Jay St., Albany 6, N. Y., Nutritionist, State Dept. of Health

Maternal and Child Health

Marcella A. Gawronski, R.N., M.A., 402 Bella Vista, Pasadena 8, Calif., Maternal and Child Health Nursing Consultant, State Dept. of Public Health
 A. W. Kuts-Cheraux, M.D., Dr. P.H., 24 Main St., Bisbee, Ariz., General Practice, Cheraux Clinic
 Hannah D. Mitchell, B.S., State Health Department, Atlanta 3, Ga., Maternal and Child Health Consultant

Public Health Education Section

- Isabel C. Bell, A.B., 1551 Franklin Ave., Mineola, N. Y., Director of Education, Nassaw County Cancer Committee
- Ralph H. Boatman, Jr., B.Ed., 917 Mayo St., Carlinville, Ill., Student, School of Public Health, Univ. of North Carolina
- LeRoy Davenport, D.V.M., 218 Centennial Bldg., Springfield, Ill., Asst. Supt., State Division of Livestock Industry
- Kathleen K. Devine, Metropolitan Life Insurance Co., 1 Madison Ave., New York 10, N. Y., Program Planning and Research, Safety Bureau, Health and Welfare Division
- Dean Halliday, 1900 Euclid Ave., Cleveland, Ohio, Public Relations Director, Anti-Tuberculosis League and Univ. Hospitals
- Salvador Hernandez, M.D., 603 West 138th St., New York, N. Y., Director, Roosevelt Hospital, Guatemala City, Guatemala, C. A.

NEWS FROM THE FIELD

U. S. PRESIDENT'S 1947 HEALTH MESSAGE

On May 19, the President of the United States transmitted to Congress a message recommending the development and enactment of national health and disability insurance programs. He summarized the outlines of a long-range health program as presented in his earlier health message of 1945. Such a program, he declared, must include:

1. Adequate public health services, including an expanded maternal and child health program
2. Additional medical research and medical education
3. More hospitals and more doctors in all areas of the country where they are needed
4. Insurance against the costs of medical care
5. Protection against the loss of earnings during illness

In making a plan for adequate medical and dental care for children, for early care of illness now often delayed because of the high cost of medical care, for the better distribution of doctors, dentists, and hospital facilities, the President said "A national health-insurance program is a logical extension of the present social security system which is so firmly entrenched in our American democracy. Of the four basic risks to the security of working people and their families—unemployment, old age, death, and sickness—we have provided some insurance protection against three. Protection against the fourth—sickness—is the major missing element in our national social-insurance program."

On May 20, Senators Murray, Wagner, Pepper, Chavez, McGrath, and Taylor introduced Senate Bill 1320 designed to carry out the purposes stated in the President's message. This bill

follows very closely the Wagner-Murray-Dingell bill of last year's Congressional Session but strengthens the provisions guarding against federal control. In the new bill, administration is vested in a National Health Insurance Board rather than in the single person of the Surgeon General of the U. S. Public Health Service. It also provides for a national Medical Advisory Council.

The bill provides for a national insurance system of prepaid personal health services with decentralized administration to be carried out by state and local agencies, authorizes federal grants-in-aid to pay premiums for those unable to pay premiums out of their own earnings, for the establishment of community-wide public health and maternal and child health services, and for medical research or professional education relating to the prevention of disease and disability. It covers all employed and self-employed, including domestic and agricultural workers now largely excluded from the benefits of the Social Security Act.

DR. HILLEBOE, NEW YORK STATE HEALTH COMMISSIONER

On July 1, 1947, Governor Dewey of New York announced the appointment of Herman E. Hilleboe, M.D., as New York State Health Commissioner. He was previously assistant Surgeon General and Associate Chief of the Bureau of State Services of the U. S. Public Health Service. Since 1942, he has been in charge of tuberculosis control activities of the Service.

Dr. Hilleboe received the degree of Doctor of Medicine from the University of Minnesota Medical School; had graduate training in pediatrics at the University Hospitals, and received the

Master of Public Health degree from the Johns Hopkins School of Hygiene and Public Health.

Shortly after assuming office, Dr. Hilleboe left for a three week tour of Europe to study health and tuberculosis problems on the continent and to attend three international meetings. He attended the meeting in Paris July 27 and 28 of the International Union Against Tuberculosis as one of the five American delegates representing the National Tuberculosis Association. He was the American delegate on the four-man Expert Committee on Tuberculosis of the World Health Organization's Interim Commission, and attended a meeting in Paris with the Danish, English, and Russian members of this Expert Committee. He was also the American representative of the U. S. Public Health Service at the International Congress on Microbiology in Copenhagen, July 17-18.

Dr. Hilleboe is a member of the following scientific societies: American College of Chest Physicians, American Epidemiological Society, American Medical Association, American Public Health Association, of which he is a Fellow, American Statistical Association, American Trudeau Society, Mexican Society Against Tuberculosis, National Tuberculosis Association, and the Tuberculosis Association of India.

Dr. Hilleboe has over 60 publications in the medical and public health literature published from 1931 to 1947. He is co-author with Dr. Russell H. Morgan, Professor of Radiology at Johns Hopkins Medical School, of the book, *Mammography of the Chest*, published in 1945.

Dr. Hilleboe has returned to the United States and is now in active charge at the New York State Health Department. Among the programs which have been set for this department is the elimination of tuberculosis in the state within the next 25 years.

NEW JERSEY'S STATE HEALTH DEPARTMENT REORGANIZATION

Both the Assembly and Senate of New Jersey passed the State Health Department Reorganization Bill by large majorities. It provides for a State Health Department and a Commissioner charged with the duty of formulating comprehensive policies for the promotion of public health and the prevention of disease within the state. It provides also for a Public Health Council with power to make sanitary regulations. The Commissioner is empowered to establish, with the approval of the Public Health Council, such health districts as may seem necessary.

The Public Health Council under the new law prescribes the qualifications of health officers and sanitary inspectors for local health departments. No medical qualification for health officers is written into the law.

Although included in the bill as introduced, the Act as passed does not require a public health degree or at least a year of graduate study in public health as a qualification of the state health commissioner.

A county health department bill, also introduced into the recent legislature, failed to reach the floor of either house.

The members of the new Health Council who have been appointed for terms of from one to seven years respectively are as follows:

- Harvey N. Davis, Sc.D., President, Stevens Institute of Technology
- Wheeler McMillen, Editor, *Form Journal*
- Frederick P. Lee, M.D., Health Officer, Paterson
- Walter G. Alexander, M.D., former State Board of Health member, and practicing physician
- Marcus W. Newcomb, M.D., practicing physician
- Florence M. Farr, lay member of New Jersey State Organization for Public Health Nursing and other nursing and health organizations
- Henry N. Landall, Professor of Municipal and Sanitary Engineering, Rutgers University

NATIONAL CANCER INSTITUTE OF CANADA CREATED

To coördinate all efforts in cancer control in Canada on a national basis, the Minister of the National Health and Welfare called a conference of representatives from all organizations working in the cancer field in Canada, as a result of which the National Cancer Institute of Canada was organized. It will (1) provide for the education and subsistence of cancer research workers; (2) provide undergraduate and post-graduate education for physicians, and attempt to establish a uniform system of reporting cancer cases and deaths throughout the Dominion; (3) continue the lay educational program now being conducted by the Canadian Cancer Society; and (4) raise funds to support the work of the institute.

Dr. Allan W. Blair, Regina, Sask., was recently appointed Managing Director. The first project planned by the institute is an immediate survey of all cancer facilities for diagnosis, treatment, and research in Canada.

STATE AID FOR LOCAL HEALTH DISTRICTS IN CONNECTICUT

Under the headline, "A Milestone in Connecticut Public Health Program," the Connecticut State Department of Health *Weekly Bulletin* reports the passage on June 4 of House Bill 175 by the State's General Assembly. A similar bill had been defeated in three previous successive Assembly sessions.

The Health District Bill permits two or more towns, cities, and boroughs to unite into a locally self-governing district department of health, and authorizes the state to pay up to 50 per cent of the cost of operating such a department. This is limited by a ceiling of \$4,000 available to any one municipality, and \$20,000 to any one district. An appropriation of \$25,000 was made for financing district health departments during the biennium 1947-1949.

The Connecticut *Bulletin* points out that, although this is a modest appropriation, "it represents the beginning of a program which may eventually make extensive public health services available to all Connecticut communities." It urges communities to "convince local boards of selectmen that full-time local departments of health are desirable and necessary." "First come—first served," it urges.

HOUSING SEMINAR

In June the Department of Public Health of Yale University held a three day Seminar on the Hygiene of Housing in coöperation with the A.P.H.A.'s Committee on the Hygiene of Housing, the Connecticut State Health Department, and the New England districts of the U. S. Public Health Service and the Federal Public Housing Authority. The purpose of the Seminar was to bring to the attention of state and local health and housing officials up to date information on housing. "That health departments will continue to have an increasing stake in housing activities is self-evident," declared the program announcement.

Among the speakers were C.-E. A. Winslow, Dr.P.H., on the "Basic Principles of Healthful Housing," and Allan A. Twichell on "Appraising the Quality of Urban Housing." They are respectively Chairman and Technical Secretary of the Association's Committee on the Hygiene of Housing.

The conference was attended by a representative group of health officers, sanitation personnel, and housing officials from the Northeastern States.

INTERNATIONAL CONGRESS OF NURSES

The first post-war Congress of the International Council of Nurses was held in Atlantic City in May. It was attended by 6,600 professional nurses, 748 of them from 38 nations outside of the United States. This was the first

Congress of this Council since the one held in London in 1937. The next Congress, celebrating the fiftieth anniversary of its founding, will be held in Stockholm in June, 1949.

The Congress adopted the findings of a Study Committee calling for an enlarged program, including a Bureau of Education in the Council, and for a return of headquarters to London as soon as feasible.

Officers elected at the May meeting were:

President—Gerda Hojer, President, Swedish Nurses' Association

First Vice-President—Mary I. Lambie, Director, Division of Nursing, New Zealand Health Department

Second Vice-President—Katherine J. Densford, President, American Nurses' Association

Third Vice-President—Grace M. Fairley, formerly Director of Nurses, Vancouver (B. C.) General Hospital

Treasurer—G. E. Davies, formerly Registrar, General Nursing Council for England and Wales

MISSOURI PUBLIC HEALTH ASSOCIATION

The Missouri Public Health Association elected the following new officers at its recent Annual Meeting:

President—William J. Dixon, Kansas City

President-Elect—Alexander E. Murphy, D.D.S., St. Louis

1st Vice-President—Lucille Whitesides, R.N., Jefferson City

2nd Vice-President—William F. McCarthy, M.D., Independence

Treasurer—John Buxell, St. Louis

Secretary—Margaret Willhoit, R.N., Kansas City

GEORGIA PUBLIC HEALTH ASSOCIATION

The Georgia Public Health Association elected the following new officers at its Annual Meeting held in Atlanta, June 9-11.

President—M. E. Winchester, M.D., Brunswick

President-Elect—C. A. Henderson, M.D., Savannah

Vice-President—J. A. Willman, Columbus

Secretary-Treasurer—Louisa G. Lenert, Atlanta

Representative on A.P.H.A. Governing Council—Louisa G. Lenert, Atlanta

PUBLIC HEALTH ASSOCIATION OF NEW YORK CITY

The Public Health Association of New York City met at the Hotel Martinique on the afternoon and evening of June 2. Two section meetings were held in the afternoon, one on environmental sanitation and one a spirited panel discussion on the future of voluntary health agencies in the light of increasing appropriations and trained personnel in official federal, state, and local health departments. The speakers at the dinner meeting were Dr. Jerome S. Peterson on "Public Health Progress as I Saw it in China," and Ralph G. Albrecht, attorney, on "The Nuremberg Trial."

Dr. John L. Rice, former City Health Commissioner of New York was elected President. Other officers were:

1st Vice-President—Helen Crosby

2nd Vice-President—Dr. Jacob A. Goldberg

Secretary-Treasurer—Charles A. Freck

Representative to the A.P.H.A. Governing Council—Frank Kiernan

Members of the Executive Board—Jean South, Sophie P. Williams, Dr. Michael Antell, Dr. Thomas D. Dublin, Dr. Franklin Foote, Dr. Jerome S. Peterson, and Mr. Kiernan.

IDAHO PUBLIC HEALTH ASSOCIATION

The following officers were elected to serve for the year 1947-1948 at the recent Annual Meeting of the Idaho Public Health Association.

President—H. D. Cramer, M.D., Moscow

1st Vice-President—Clara S. Evans, Sandpoint

2nd Vice-President—A. R. McCabe, M.D., St. Maries

3rd Vice-President—A. M. Popma, M.D., Boise

4th Vice-President—Sister M. Alma Dolores, Boise

5th Vice-President—Mrs. C. S. Bosquet, Pocatello

Secretary—John W. Wright, Boise

Treasurer—Frances Goodwin, Boise

Representative to A.P.H.A. Governing Council—L. J. Peterson, Boise

NORTH DAKOTA PUBLIC HEALTH ASSOCIATION

The fourth annual meeting of the

North Dakota Public Health Association was held in Fargo in May. Among the items on the program was a panel discussion on "What are Our Public Health Liabilities and Assets," led by Carl E. Buck, Dr. P. H., Field Director of A.P.H.A.

The following officers were elected for the coming year:

President—A. L. Bayone

Vice-President—Everett Lobb

Secretary—Mrs Margaret Watts

Treasurer—Howard C Hammond

Advisory Council Members — Mrs. Jerome Evanson, Elvira Smith, Pat Steele, Jerome Svore, Caspar Walhowe, Gladys Wentland.

KANSAS PUBLIC HEALTH ASSOCIATION ELECTS NEW OFFICERS

At its Annual Meeting held May 27-28, the Kansas Public Health Association elected the following officers to serve for the next year:

President—Charles A Hunter, Ph.D., Topeka

Vice-President—Manila Robbins, Topeka

President-Elect—J. E. Wolfe, M.D., Wichita

Secretary—Evelyn Ford, Topeka

Treasurer—Arthur Wallach, Olathe

CONNECTICUT PUBLIC HEALTH ASSOCIATION

The Connecticut Public Health Association reports the following new officers elected at its Annual Meeting on May 27:

President—Thomas J. Bergin, M.D., Greenwich

President-Elect—George B. Davis, M.D., Milford

Vice-President — Sterling P. Taylor, M.D., North Haven

Secretary-Treasurer—Jessie P. Halbert, Meriden

COLORADO PUBLIC HEALTH ASSOCIATION

At the annual meeting of the Colorado Public Health Association at Colorado Springs in May, 1947, the following officers were elected for the coming year:

President: Alfred E. Kessler, Executive Secretary, Denver Tuberculosis Society

Vice-President: Robert Downs, D.D.S., Director of Dental Hygiene, Colorado State Health Department

Secretary: Norma Johannis, Director of Health Education, Colorado State Health Department

Treasurer: Mrs. Georgia Ball Travis, Director of Social Service, Colorado General Hospital

ILLINOIS PUBLIC HEALTH ASSOCIATION

The new officers elected at the recent Annual Meeting of the Illinois Public Health Association are as follows:

President—E. A. Piszczek, M.D., Chicago

President-Elect — Maude B. Carson, R.N., Springfield

Secretary-Treasurer—Harold M. Cavins, Ed.D., Charleston

SOCIAL HYGIENE LIFE MEMBERSHIP TO DR. CHESLEY

Dr. Albert J. Chesley, for more than a quarter of a century the Executive Officer of the Minnesota State Department of Health, has been awarded an honorary life membership in the American Social Hygiene Association. The *Journal* cannot hope to reprint all of the accomplishments listed in the citation accompanying this award which says among other things, "nobody could very well think of health in Minnesota's last forty years without Chesley there." However, the American Social Hygiene Association, (1790 Broadway, New York 19) has printed the citation in a leaflet whose cover page has a photograph of Dr. Chesley. They will be glad to send this to anyone requesting it while the supply lasts.

PUBLIC HEALTH NURSE ON STAFF OF HARVARD SCHOOL OF PUBLIC HEALTH

Frances M. Frazier, R.N., has been appointed Instructor in Public Health Nursing in the Department of Public Health Practice of the Harvard School of Public Health, beginning with the academic year 1947-1948. This represents the first appointment of a public health nurse to the staff of the school. Miss Frazier has just completed her

work for the M.P.H. degree in the Harvard School. During the war she served for nearly three years as nursing consultant to Yugoslavia under UNRRA.

DR. COURTNEY SMITH DIES IN AIRPLANE ACCIDENT

Courtney Smith, M.D., Dr. P. H., Medical Director, American National Red Cross, Washington, D. C., was among the 50 persons killed in the wreck of a Capitol Airliner on June 13 in the mountains of West Virginia.

Dr. Smith, a native of Michigan, was a graduate in medicine of the University of Oregon in 1933, with a Doctorate in Public Health from Yale in 1938. He had been a county health officer in Oregon, Assistant Health Officer in Portland, Oregon, and Assistant Commissioner of Health of the Territory of Alaska prior to his service in the war, which included a number of months in Germany. He was appointed Medical Director of the Red Cross recently when Dr. G. Foard McGinnes was made Vice-Chairman in charge of health services.

Dr. Smith joined the American Public Health Association in 1937 and was elected a Fellow of the Health Officers Section in 1941. He had served in many representative capacities, most recently as alternate delegate of the American Red Cross to the National Health Council.

TEN YEARS OF JANE COFFIN CHILDS CANCER FUND

Stanhope Bayne-Jones, M.D., Director, at a recent 10th Anniversary dinner meeting, reported that the Jane Coffin Childs Memorial Fund had expended nearly a million dollars in cancer research and had made total appropriations of \$1,343,000 through 1950. Annual appropriations have risen from \$10,000 in 1937 to \$171,000 in 1947.

Located at Yale University, the operation of the fund is not restricted to any single institution. From 40 to 60 per

cent of annual appropriations have been given to Yale. The present ratio is about 50 per cent.

NURSES IN PUBLIC HEALTH

The annual report of the U. S. Public Health Service on the number of nurses employed for public health work in the United States has recently been published. It shows 21,500 public health nurses employed on January 1, 1947, an increase of only 4 per cent over the previous year. However, the three previous years registered slight declines. Nearly three-fourths of all public health nurses reported were employed by local official health agencies or school boards. The complete analysis, made up of 14 statistical tables, is available from U. S. Public Health Service, Washington, D. C.

M.P.H. DEGREES TO HARVARD-M.I.T. SCHOOL OF PUBLIC HEALTH GRADUATES

At the Harvard University Commencement exercises in June, 43 living graduates of the former joint Harvard-Massachusetts Institute of Technology School of Public Health were awarded the degree of Master of Public Health. The school was in operation between 1913 and 1922, during which time those who have now received the Master's degree received the "Certificate in Public Health."

REPRINTS

Reprints of the article by Jessie M. Bierman, M.D., and Donald R. Caziarc of the California Department of Public Health, which appeared in the April issue of the *American Journal of Public Health* are available gratis in lots of five or ten copies to public health officers, school nurses, and administrators, parent-teachers study groups. Address Mrs. Mary Rogers Miller, 1209 Crenshaw Boulevard, Los Angeles 6, Calif.

KANSAS ESTABLISHES A CANCER REGISTRY

The University of Kansas School of Medicine and Hospital, under the direction of the Division of Cancer Control of the State Board of Health, is establishing a cancer registry. Abstracts of about 800 cases of cancer for the year 1945 from the records of the department of pathology have been completed. Cancer records from the William Newton Memorial Hospital and St. Mary's Hospital at Winfield have also been received. This is one of the initial steps leading to the establishment of diagnostic cancer clinics as approved by the coöperative cancer control group in Kansas, the Kansas Medical Society, the Kansas Division of the American Cancer Society, and the Kansas State Board of Health.

WEST VIRGINIA RAPID TREATMENT CENTER TRANSFERRED TO STATE HEALTH DEPARTMENT

The Kanawha Valley Medical Center, the state's rapid treatment center, South Charleston, was transferred April 1 from the federal government to the State Department of Health. The present staff of forty-five, including two doctors, is being retained. More than 10,000 persons were treated during the three years the center was operated by the government. Of these, more than one-fourth were under 21 years of age, 17.4 per cent between 18 and 21, and 1.3 per cent infants under 1 year of age. The cost per patient for the treatment of syphilis has been about \$46. After July 1 the state is expected to assume about 30 per cent of the cost of the center.

TOMPKINS COUNTY (N. Y.) APPOINTS BOARD OF HEALTH

Tompkins County, with a population of nearly 50,000 and including the City of Ithaca, is the fourth New York county to organize under the provisions

of the 1947 amendment to the Public Health Law whereby a county health department receives state reimbursement for 75 per cent of the first \$100,000 spent for public health work, and 50 per cent of amounts in excess of \$100,000. The county supervisors recently appointed a county board of health and are recruiting a county health commissioner and other personnel.

NEW CITY-COUNTY HEALTH DEPARTMENT IN ILLINOIS

Among the war emergency measures initiated in a number of Illinois communities was an arrangement whereby the medical health officer of the chief city in a county also supervised the health work of the rest of the county. Such an arrangement was in effect in Adams County where the Quincy Health Officer, Dr. O. H. Collins, gave general supervision to the health work in the county as well.

On April 1, 1947, in a referendum election, the citizens of Adams County voted the consolidation of the city and county health departments by a plurality larger than any received by candidates elected to office. The new County Board of Health will assume jurisdiction over the entire county population of more than 65,000 on March 31, 1948.

GEORGE W. FULLER AWARD TO MAC H. MC CRADY

Mac H. McCrady, Chief, Division of Laboratories of the Ministry of Health, Province of Quebec, was selected as the recipient for the George W. Fuller Memorial Award by the Canadian Section of the American Water Works Association during their 27th annual meeting held in Montreal during April, 1947. The citation read:

For notable accomplishments in the water works field and in the affairs of this association especially in the interpretation of laboratory analyses, and in the development of "Standard Methods for Water Examination."

WASHINGTON REPORT ON THE MEDICAL SCIENCES

On June 9 the weekly news letter, *Washington Report on the Medical Sciences*, began publication. Its aim is to report highlights of nationally significant developments in the week's news, to interpret, and to forecast now and then. Its editor is Gerald G. Gross, since 1930 science writer of the *Washington Post*, and currently consultant on public relations to the Surgeon General, U. S. Army. He was also special consultant for the recent medical survey report on the bituminous coal industry. (526 Bond Building, Washington, D. C. \$50 a year.)

PUBLIC HEALTH OFFICERS HONORED

At a joint dinner of the Canadian Public Health Association and the State and Provincial Health Authorities of North America in Quebec May 22 certificates of honorary membership in the Canadian Association of Public Health were presented to Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service, and to Dr. Walter L. Bierring, President of the State and Provincial Health Authorities of North America and Commissioner of Health of Iowa, both of whom addressed the group.

YOUTH SERVICE NEWS

In December, 1946, the New York State Youth Commission (24 James Street, Albany) published vol. 1, no 1 of *Youth Service News* as an experiment in pooling knowledge and experience in the youth service field. It announced that frequency or even continuation of publication would depend on the need and whether the need is met in this way. Its announced intention of "no desire to publish for the sake of publishing," should prevent editorial hardening of the arteries. At any rate vol. 2 of *Youth Service News* came out in April, 1947.

CORRECTION

DENNYS L. LYALL,[†] reported in June as health inspector of Salisbury Southern Rhodesia, Africa, was incorrectly reported as previously Assistant Director of Antitoxin, Serum, and Vaccine Laboratories, New York State Department of Health. HAROLD W. LYALL, PH.D.,* holds the latter position and is still in Albany.

PERSONALS

Central States

AUGUST BAIER, M.D.,* has been appointed Medical Director, United States Rubber Company, Detroit, Mich. Dr. Baier was formerly Medical Director, Solar Aircraft Co., Des Moines, Ia.

F. C. BEELMAN, M.D.,* Secretary and Executive Officer of the Kansas State Board of Health, was elected president of the Conference of State and Provincial Health Authorities of North America, at the 1947 session held May 20 and 21 at Quebec, Canada.

SETH L. COX, M.D.,[†] formerly Medical Director of the Kansas Tuberculosis and Health Association, has been appointed Executive Secretary, succeeding C. H. LERRIGO, M.D.,* who becomes Executive Secretary Emeritus.

JOSEPH E. FLANAGAN, JR.,[†] formerly Industrial Hygiene Engineer, Ohio State Health Department, has been appointed Industrial Hygiene Consultant, District No. 3, U. S. Public Health Service, Chicago, Ill.

ROLLA N. HARGER, PH.D., Professor of Biochemistry and Toxicology in the Indiana University School of Medi-

NEWS FROM THE FIELD

Vol. 37

cine, Bloomington-Indianapolis, has joined the staff of the Indiana Bureau of Industrial Hygiene as consultant on toxicology.

R. M. HEILMAN, M.D.,† has returned to service with the Kansas State Board of Health, as Director of the newly created Division of Hospital Survey and Construction. Dr. Heilman was formerly Director of the state health department's Industrial Hygiene Division, having been appointed to that Division when it was established. For the last several months he has been practising internal medicine at Winter Veteran's Hospital.

ROSCOE L. SENSENICH, M.D., practising physician of South Bend, Ind., was made Presiding President-elect of the American Medical Association for 1947-48 at the Centennial Meeting of the Association in Atlantic City in June.

ALFRED H. WIETERS,* formerly Director of the Division of Public Health Engineering of the Iowa State Department of Health, has become a sanitary engineer with the U.S.P. H.S., assigned to the hospital construction program.

ALEXANDER WITKOW, M.D.,* formerly city-county health commissioner of Delaware, Ohio, has been appointed director of the Bureau of County Health Work in the West Virginia State Department of Health, to succeed NORMAN G. ANGSTADT, M.D.,† resigned.

Eastern States

CONRAD BERENS, M.D., of New York City, was elected vice-president of the National Society for the Prevention of Blindness at the June meeting of the Board of Directors. Dr. Berens is Director of the Graduate Course

of the Department of Ophthalmology, New York University, and Executive Surgeon of the New York Eye and Ear Infirmary and Affiliated Institutions.

CHESTER S. BOWERS,* acting director since March 1, 1946, was appointed Director, Bureau of Public Health Information, Connecticut State Department of Health, effective April 1, 1947.

JOHN E. GORDON, M.D.,* Professor of Preventive Medicine and Epidemiology, Harvard University, Boston, Mass., was recently awarded the Liberty Cross by His Majesty the King of Norway, in recognition of services to Norway during World War II.

EDWARD S. HOPKINS,† Associate Engineer of the Baltimore Department of Public Works, has been appointed Chairman of the Committee on Standard Methods for the Examination of Water and Sewage of the American Chemical Society.

HELEN E. KINNEY,† former Instructor, Public Health Nursing Department, Seton Hall College, Newark, N. J., has been appointed Assistant Director, Division of Public Health Nursing, St. Louis University, St. Louis, Mo.

HENRIETTA LANDAU, R.N.,* has been appointed Assistant Professor of Nursing Education at New York University's School of Education. She was formerly consultant public health nurse with the U. S. Public Health Service.

HUGH R. LEAVELL, M.D.,* was elected President of the Massachusetts Central Health Council on May 1.

ROMAYNE W. LILOIA,† formerly Supervisor, Visiting Nurse Association, Scranton, Pa., has been appointed Consulting Public Health Nurse, Division of Local Health Administration, North Carolina State Board of Health.

* Fellow, A.P.H.A.

† Member, A.P.H.A.

HAROLD P. LYON, M.D., former Director of Medical Services, Sanitation, and Preventive Medicine Division, Royal Canadian Air Force, has been appointed Industrial Physician and Medical Director to "Hartford Group," Small Industrial Plants, in Hartford, Conn.

NEW APPOINTMENTS TO THE MASSACHUSETTS DEPARTMENT OF HEALTH:

WILLIAM D. WELLOCK, D.M.D., a Navy veteran and recent graduate of the Harvard School of Public Health, as Director of the Division of Dental Health.

GRACE E. LUTMAN, M.D., Dr.P.H.,† former assistant state district health officer, New York State Department of Health, as Supervisor of Clinics for Crippled Children.

FRANCIS W. HOOPER, M.D., as district health officer of the South Metropolitan district with headquarters in Quincy. Prior to his appointment, Dr. Hooper saw 18 months' service in the European Theatre of Operations as a captain in the Medical Corps, AUS.

CLAUDE W. MUNGER † was recently appointed a member of the hospital advisory committee of Associated Hospital Service—New York's Blue Cross Plan. Dr. Munger is director of St. Lukes Hospital and professor of hospital administration at Columbia University.

CHANGES IN NEW YORK STATE DEPARTMENT OF HEALTH:

Assistant District Health Officers appointed. WILLIAM R. DONOVAN, M.D., Geneva; FRANK R. FRECKLETON, M.D.,‡ Utica; MICHAEL LIAPAL, M.D.,‡ Middletown; CLAYTON M. STEWARD, M.D.,‡ Binghamton; VINCENT H. HANDY, M.D.,‡ Buffalo.

JOHN M. CHAPMAN, M.D.,‡ district health officer in the Saranac Lake

District, resigned from the department to become Assistant Director of the Medical Section of the Health Department of the City of Los Angeles, Calif.

DON M. GRISWOLD, M.D.,* district health officer in the Geneva district, retired effective May 31.

RAY E. TRUSSELL, M.D.,‡ was appointed Epidemiologist in the Division of Communicable Diseases.

H. C. MILES, M.D.,‡ and W. C. SPRING, JR., M.D.,‡ formerly apprentice epidemiologists on the staff of the State Department, were appointed deputy commissioners of health of Cattaraugus and Rensselaer County Health Departments, respectively.

JULIA MACPHILLIPS, consultant public health nurse in social hygiene work, retired from State service after serving 27 years in the department.

HOWARD A. RUSK, M.D.,‡ Chairman of the Department of Rehabilitation and Physical Medicine of New York University, New York, N. Y., and Associate Editor of *The New York Times*, was recently awarded the degree of Doctor of Science by the University of Missouri.

CHARLES C. SPENCER, C.E., has been appointed Assistant Professor of Sanitary Science, School of Public Health, Columbia University, effective July 1, 1947. Major Spencer's recent experience includes sanitary and public health engineering assignments with the Dorr Company in the United States and Europe, the U. S. Public Health Service in the United States and Central America, and the Sanitary Corps, U. S. Army, in the United States and Brazil. His appointment is coupled with an enlarged curriculum in the regular program of gradu-

* Fellow, A.P.H.A.

† Member, A.P.H.A.

ate engineering training for public health engineers which has been offered since 1921 by the School of Public Health.

MAJOR GENERAL MORRISON C. STAYER,* U. S. Army, Retired, at present chief of the Bureau of Tuberculosis Control, Pennsylvania State Department of Health, was decorated with the Legion of Merit at Carlisle Barracks, Pa., in April, 1947. The citation refers to General Stayer's control of typhus, typhoid fever, and other epidemics in the American Zone of occupied Germany.

HELEN E. WATKINS† has resigned as Director of Recruiting, Training and Placement of Personnel of the New York State Charities Aid Committee on Tuberculosis and Public Health to become Executive Secretary of the Arizona Anti-Tuberculosis Association with headquarters in Phoenix.

Southern States

MAJOR GENERAL RAYMOND W. BLISS,

on June 1 became the new Surgeon General of the Army, succeeding

MAJOR GENERAL NORMAN T. KIRK who will retire from active duty.

Since January 1, 1946, General Bliss has served as Deputy Surgeon General.

BRIG. GENERAL GEORGE E. ARMSTRONG assumes the duties of

Deputy Surgeon General.

RUTH BUNKER, R.N., on July 1 joined

the West Virginia State Department of Health as consultant nurse in

tuberculosis. Before joining the armed forces she was a public health

nurse in Braxton County and with the Fayette County Tuberculosis Association.

CARL M. GAMBILL, M.D.,† formerly

Director of Local Health Work in the Kentucky State Health Department,

is now Associate Editor, Division of Publications, Mayo Clinic, Rochester, Minn.

JOHN M. HOOPER, M.D., M.P.H.,* has

resigned from his position as Director, Amarillo Health Department, Amarillo, Texas, to go into private practice.

GRACE I. LARSEN, R.N.,† has been ap-

pointed Supervising Nurse, U. S. Pub-

lic Health Service at Weld County

Health Department, Greeley, Colo.

Miss Larsen was formerly assigned

Supervising Nurse, Marion County

Health Department, West Virginia.

NELL MCKEEVER† has been appointed

Health Education Consultant, Office

of Health Education, U. S. Public

Health Service, Brookline, Mass.

Miss McKeever was formerly Health

Educator of the City-County Health

Department, Muskogee, Okla.

WILLIAM GREGORY MORGAN, M.D.,†

former Health Officer, Clark-Mont-

gomery Co., Kentucky, has been ap-

pointed Medical Director of the

General Electric Co., Owensboro, Ky.

JAMES A. MORROW† has been appointed

Office Manager, E. L. Miller Welding

Contractor, West Chester, Pa. He

was formerly Assistant Sanitarian,

U. S.P.H.S., City Health Department,

Charlotte, N. C.

MORRIS A. NUSSBAUM† has been ap-

pointed Sanitary Chemist, Kingston

City Laboratory, Kingston, N. Y.

He was formerly Chemist, U.S.P.H.S.,

State Hygiene Laboratory, Jackson,

Miss.

MARION L. SHADDIX, M.D.,† has been

appointed Chief Medical Officer,

Veterans Administration, Medical

Unit, Gadsden, Alabama. Dr. Shad-

dix was formerly Health Officer, Clay

and Randolph Counties.

JAMES H. STEELE† has been appointed

head of the Veterinary Public Health

Section which has been established

in the States Relations Division of the

U. S. Public Health Service. This

section will conduct demonstration

projects on the control of animal dis-

eases communicable to man and will

collect epidemiological data - perti-

nent to these diseases.

Western States

ANSTA BARR, M.S.,† has been appointed Nutrition Consultant, U. S. Children's Bureau, Federal Security Agency, Dallas, Texas. She was formerly Nutrition Consultant for the Arizona State Health Department.

ARVE H. DAHL† is Chief, Mosquito Control Section, California State Department of Public Health, Berkeley.

J. C. GEIGER, M.D.,* Director of Public Health, San Francisco, Calif., has been honored by Her Gracious and Royal Majesty, The Queen of Holland, with the Royal Order of the Crown of Orange Nassau, Officer grade. It was accompanied by the following citation: "For distinguished services to the Crown and nation during World War II and for remarkable insight and understanding of public health."

dustry, U. S. Department of Agriculture, Denver, Colo., who has served many years with the U. S. Department of Agriculture in various capacities retired on July 31, to devote himself to consulting services.

South America

SÉRVULO LIMA, M.D.,† Public Health physician of the National Department of Health of the Ministry of Education and Health of Brazil and Superintendent of the Servico Especial de Saúde Pública was granted retirement by the President of the Republic, through a recent decree. He will continue his service with the Servico Especial de Saúde Pública, where, surrounded by the well-merited confidence of the Ministry of Education and Health, The Institute of Inter-American Affairs and all his colleagues, he will continue to work with this program outlined in the Good Neighbor Policy for the health of the Americas.

Deaths

EDWARD R. BALDWIN, M.D., one of the few remaining pioneers in the fight against tuberculosis who shared in the work of EDWARD LIVINGSTON TRUDEAU, M.D., died at the age of 82 at Saranac Lake on May 6. Dr. Baldwin went to Saranac Lake in 1892 as a tuberculosis patient and remained as a close associate of Dr. Trudeau and director of the Saranac Lake Laboratory for the Study of Tuberculosis. He was one of the founders of the Trudeau Sanitarium, was president of the National Tuberculosis Association in 1915 and 1916, and was awarded the Trudeau Medal in 1927.

FRED WELDEN CAUDILL, M.D., Epidemiologist of the Kentucky State Health Department, died in Louisville on January 12, 1947 at the age of 47.

An Evaluation of the Use of BCG in the Prevention of Tuberculosis in Infants and Children*

MILTON I. LEVINE, M.D., F.A.P.H.A.

Consultant Pediatrician, Bureau of Child Hygiene, Department of Health, New York, N. Y.

OF the many attempts at vaccination or inoculation against tuberculosis, none has been more widely used or more publicized than the use of BCG vaccine.

This vaccine is a living attenuated strain of an originally virulent bovine tubercle bacillus. So marked was its attenuation after a series of cultivations on a glycerol potato bile medium, that it no longer was capable of producing progressive tuberculosis in guinea pigs, rabbits, or calves, and, although over 5,000,000 children have been inoculated with it since 1922, there is no authentic case on record of the organism having returned to its former virulence.

There is also undeniable proof that BCG vaccine as well as heat killed

tubercle bacilli produce definite protection against tuberculosis in experimental animals.

However, it has been demonstrated on numerous occasions that the fact that experimental animals receive protection from vaccines, inoculations, or drugs, does not necessarily signify that human beings will receive the same protection.

It is therefore of the greatest importance that carefully controlled studies on human beings be reported before the use of BCG vaccine is accepted as of proven value as a public health measure in the prevention of tuberculosis.

In 1926 a culture of BCG was brought to the United States by the late Dr. William H. Park of the New York City Department of Health, and in the same year the studies on immunization of children were initiated in New York City.

On the basis of this study a great deal was learned and as a result of this the following standards were set down as

* Presented before the Maternal and Child Health Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1946.

From the New York Hospital and the Department of Pediatrics, Cornell University Medical College. Aided by a grant from Mead Johnson & Company, Evansville, Indiana.

necessary for a scientific conclusion:

*Essential Factors in Study of BCG
Immunization*

1. Vaccine must be of standard strength.
2. There must be controls.
3. Controls and vaccinated cases should:
 - a. Be selected by alternation to eliminate possibility of bias.
 - b. Have identical follow-up.
 - c. Come from same locality.
 - d. Come from similar age group.
 - e. Come from similar racial group.
4. Contact with cases must be maintained.
5. Exposure conditions of cases must be known throughout study period.
6. A reliable diagnosis at death.

Throughout the years, numerous studies have been reported on the value of BCG inoculation, and the great majority of these reports have been favorable. However, with few exceptions all of these studies were inadequately controlled and very few of the factors mentioned above were considered.

In some studies the mortality rate from tuberculosis of the general population was compared with that of the vaccinated group; in others a different age group served as a control; in some the tuberculosis mortality of vaccinated children was compared with the tuberculosis mortality of previous years; in other studies the controls comprised cases where vaccination was refused; in still others the control group was less carefully followed than the vaccinated cases; in one study, only the vaccinated cases were temporarily separated from the tuberculous source.

Recently a paper has been published concerning the results of BCG vaccination in Scandinavia.⁶ In all of the countries reported the results have been favorable, but again the method of control selection is open to criticism. In Oslo and in Bergen, Norway, the tuberculosis mortality of the vaccinated group was compared with that of the general population. In Stockholm, Sweden, where excellent results were re-

ported by Wallgren no controls were used. In answer to objections that no adequate controls were used, Wallgren stated that parents very seldom refuse to consent to BCG vaccination. The studies in Norrbotten, Orebro, and Boraas, all in Sweden, were also controlled by the general population. The vaccination has also been used extensively in Denmark, but controls are almost entirely lacking.

However, in spite of inadequate controls, and the knowledge that results at the present time cannot be considered as conclusive, one cannot overlook the fact that practically all of these reports have been uniformly favorable. Notable exceptions are the studies from New York City¹ and those of Blanch, Blanch, and Liertier of Uruguay.²

The latter authors have vaccinated over 103,000 infants in Uruguay since 1930 by oral, subcutaneous, intracutaneous, and multiple puncture methods. The tuberculosis mortality among the vaccinated infants was 7 per cent as against a tuberculosis mortality of 5.2 per cent of the controls.

At the start of the work in New York City, an attempt was made to control the study by dividing the accepted children into two equal groups: those for vaccination and those to serve as controls. Under this system a physician was assigned a number of cases and told to vaccinate one-half of the group. Subsequent experience has proved that by this method of selection the general tendency was to inoculate the children of the more coöperative parents and keep the children of non-coöperative parents as controls. The effect of this error will be readily realized with the knowledge that the more coöperative parent usually brings the child to the clinic more often and follows the physician's instructions more carefully.

The arbitrary division of cases was followed from 1927 until January 1, 1933, during which time 990 children

were studied, of which 445 were vaccinated.

The results at the end of this period are shown in Table 1.

TABLE 1

Results January 1, 1933—Prior to Institution of Alternate Selection

	Cases	Tuberculosis Deaths	
		Number	Per cent
Vaccinated	445	3	0.68
Controls	545	18	3.38

The figures as of that date showed the tuberculosis mortality of the controls to be almost five times that of the vaccinated cases.

The method of selection was changed on January 1, 1933, so that alternate children were routinely vaccinated. The selection was made at headquarters as soon as the names were received and before they were assigned to staff pediatricians.

It is interesting to note the tuberculosis mortality in the two groups before and after this alternation was instituted (Table 2).

TABLE 2

Comparative Results Before and After Alternate Selection

	Cases	Tuberculosis Deaths	
		Number	Per cent
Total Cases			
BCG vaccinated	1,011	11	1.08
Controls	1,073	26	2.42
Cases 12/15/26-1/1/33 (before alternate selection)			
BCG vaccinated	445	3	0.68
Controls	545	18	3.38
Cases 1/1/33-1/1/44 (after alternate selection)			
BCG vaccinated	566	8	1.41
Controls	528	8	1.51

In the second period (January 1, 1933, to January 1, 1944) after the institution of alternate selection, the tuberculosis mortality figures were essentially the same for both the vaccinated cases and the controls.

Studies on the variables which might have been responsible for the change in comparative tuberculosis mortality brought out that the cooperation of the

vaccinated group was appreciably greater than that of the control group prior to the period of alternation, with considerably closer approximation in the latter period.¹

Other variables such as exposure, racial distribution, and economic conditions appeared to have no influence on the change. However, since the tuberculosis mortality of the vaccinated cases increased after January 1, 1933, the question arose as to whether there was any loss in activity of the BCG vaccine. A history of the BCG vaccine used in the New York study revealed the following:

The original BCG culture was obtained by Dr. William H. Park from Calmette in 1926. Strains of this culture were sent to the Mt. McGregor Sanatorium and to the Phipps Institute. This culture was used in the preparation of the vaccine until late in 1932 when it became contaminated by molds. Pure cultures were at last obtained by the antiformin method and plated on media containing aniline dyes (Loewen-

stein's and modified Petroff medium). Meanwhile, subcultures were obtained from the Phipps Institute. The cultures were used alternately for vaccine for a period of one year. After this time both cultures were used without selection. Virulence tests were made at 3 month intervals but no tests were made for potency. However, it is to be noted that the percentage of positive tubercu-

lin reactions resulting from BCG inoculations did not decrease after January 1, 1933, there being 87.1 per cent before as against 87.6 per cent after that date, but this does not rule out the possibility of a loss in potency of the cultures after the contamination.

However, it was found that in a limited number of cases where separation for 3 months before and 3 months after vaccination was possible, there was some indication that BCG inoculation might have protective value were such separation practical (Table 3).

TABLE 3

Exposed Cases Separated 3 Months before and 3 Months after Being Vaccinated or Taken Up

	Cases	Tuberculosis Deaths	
		Number	Per cent
Vaccinated	91	1 *	1.1
Controls	96	3 †	3.1

* This child was born of a mother dying of tuberculosis; was never exposed; died at 3 months of age.

† One case with no known exposure died of tuberculosis at 15 months of age.

In New York City the routine separation of children for 3 months before and 3 months after BCG vaccination to eliminate the hazards of contiguous contamination with human tubercle bacilli was not found to be a feasible or safe procedure.¹

It was therefore concluded that, as a public health measure in New York

City the routine vaccination with BCG of children from tuberculous homes was less advantageous than removal of the tuberculous subjects from the home. It is realized, of course, that a city such as New York with adequate beds for the hospitalization of tuberculous patients presents a situation entirely dissimilar from localities with lack of necessary diagnostic and hospital facilities.

Within recent months the greatest amount of attention in this country has been focused on two particular reports on the efficacy of BCG: The report on Experience with BCG Vaccine in the Control of Tuberculosis Among North American Indians, by Aronson and Palmer,² and the study on BCG of the Tice Institute in Chicago by Rosenthal.³

It is of interest to appraise these studies in the light of the standards developed as a result of the investigation in New York City.

The studies on Indians were undertaken at eight different reservations in western United States and in Alaska. Approximately equal numbers of Indians were selected for vaccination and controls (Table 4).

It is stated that "a random portion of the tuberculin-negative reactors was vaccinated . . . while the remainder served as controls." Apparently the cases were not alternated and in writing of the method of selection the authors

TABLE 4
Results of BCG Studies on Indian Reservations

	Vaccinated Cases	Tuberculosis Deaths	Controls	Tuberculosis Deaths
<i>Arizona</i>				
Pima A	259	1	263	2

Poncha	269	2	266	6
<i>Alaska</i>	497	0	464	12

state, "it is, of course, not possible to be certain that no bias was unintentionally introduced." The vaccinated and control cases balance only fairly well as to age, per cent examined annually, and degree of exposure to tuberculosis. But the studies in New York would seem to indicate that this alone is insufficient and that the impartial selection of cases by alternation is an essential factor in adequate experimentation. It is also necessary to point out the arbitrary ratings of exposure given contact cases in the paper of Aronson and Palmer. For instance, to quote: "The highest rating 3 was limited 'to very intimate contact with a sputum-positive case.'" There is no consideration given, apparently, to whether the case was Gafky I or Gafky X as long as organisms were found in the sputum.

The question of accurate diagnosis at death also must be considered in the review of the study on American Indians. The basis for the diagnosis of the tuberculosis deaths is inadequate when it is reported that "in the control group some of the deaths which were assigned to non-tuberculous causes may actually have been a consequence of tuberculosis." The New York study shows clearly the necessity of an autopsy before a diagnosis of a tuberculous death can be considered entirely accurate.⁴

However, the results of BCG vaccination on the American Indian are reported as favorable and must at least be considered as additional evidence that BCG vaccine has a degree of effectiveness in the prevention of tuberculosis.

The report of ten years' experience with BCG in the City of Chicago also presents favorable results. In this study the cases were alternated without selection, the children were grouped into two general categories; those with no known exposures to tuberculosis (non-contact cases), and those from tuberculous households (contact cases).

The results of the non-contact cases are reported in Table 5.

TABLE 5
Tuberculosis Mortality of Non-Contact Cases (Chicago Study)

	Number of Cases	Tuberculosis Deaths	Tuberculosis Mortality
Vaccinated	1,204	1	0.08%
Controls	1,213	4	0.33%

It is interesting to note that among these "non-contact" controls the tuberculin tests were positive in 9 per cent at the age of 2 years; 15 per cent at the age of 3 years, and 35 per cent at the age of 5 years. This high morbidity is explained by the fact that the children came largely from a district in Chicago where the tuberculosis mortality ranged as high as 330 per 100,000.

The children who came from tuberculous homes were separated for varying periods of time in foster homes before and after vaccination or for a similar time in the case of controls. Rosenthal states that "BCG should not be expected to accomplish more than other forms of vaccination where protection is afforded against a casual contact with the respective disease, and where isolation is strictly enforced."

The results of contact cases in the Chicago study are shown in Table 6.

TABLE 6
Tuberculosis Mortality of Contact Cases (Chicago Study)

	Number of Cases	Tuberculosis Deaths	Tuberculosis Mortality
Vaccinated	98	0	0%
Controls	63	3	4.53%

In April, 1946, it was my privilege to visit the Tice Institute in Chicago to become more fully acquainted with the methods used and the results obtained. In this study the method of alternate selection was used, vaccinated cases were separated from contacts before and after inoculation, and controls separated for a similar period of time.

However, several serious factors deserve consideration. Over 300 children

have been lost in the course of the study, and in view of the low tuberculosis mortality rate such a loss cannot be ignored. A more extensive follow-up of exposure to tuberculosis after the children return from the foster homes would also be advisable.

Rosenthal³ states: "These infants were not returned to the source case, but were kept in a permanent foster home. Fortunately, the State of Illinois forbids a child under 16 years of age to live with a tuberculous member who has a "positive sputum." However, inquiries reveal that separation is not strictly enforced and that the tuberculous member of the family may legally sleep in an apartment next door or around the corner but return to his own home during the day.

In the Chicago study, therefore, the exposure to tuberculosis is frequently unknown once the children return from the foster homes.

No information is given in the Chicago study as to the racial percentages in each group, although of the 10 tuberculosis deaths as of April, 1946, 7 were of Negro children. But here again the results are definitely favorable and contribute added evidence as to the probable efficacy of the vaccine.

In the final analysis, the efficacy of BCG vaccine must be determined on the basis of tuberculosis mortality or at least on its ability to prevent the caseous-pneumonic type of pulmonary lesion. The fact that children or nurses vaccinated with BCG show less frequently evidence of pulmonary tuberculous lesions on roentgenographic examination is in itself inadequate and almost valueless evidence.

The first tubercle bacilli inhaled into the lungs produce an area of inflammation about the focal site. This appears as a shadow on chest roentgenograms and is part of the primary complex of tuberculosis, the reaction to the first infection with the tubercle bacillus. Co-

incident with this the tissues become allergic, and when this area of inflammation subsides, no other inhaled tubercle bacilli are capable of producing again such an area of inflammation. The tissue reaction has been changed by the development of allergy.

When one inoculates the arm or the leg with BCG vaccine a focal reaction occurs, the lymph nodes draining the area enlarge and the tissues become allergic to tuberculin. In other words, the vaccination produces a primary complex in the arm or leg, and one would not expect the typical primary pulmonary infiltration on later exposure to tubercle bacilli. Yet this fact is overlooked completely in many reports which stress the lack of x-ray evidence of pulmonary inflammation after inoculation with BCG. A number of these reports are based on studies of persons entering nursing training schools where certain of the negative reactors to tuberculin testing were vaccinated with BCG. The reports on the American Indians as well as the Chicago study claim effectiveness for the vaccine in the lessened morbidity of the vaccinated cases as evidenced by pulmonary roentgenographic findings.

Despite the fact that up to the present time no study on the effectiveness of BCG fulfils all the essential research qualifications, there appears to be considerable circumstantial evidence in its favor. This makes the continuance of BCG research essential. New studies should be undertaken in districts where tuberculosis mortality is high. These new studies and those already in progress should be checked by some central regulating organization which should be responsible for standardizing the vaccine, correlating methods of investigation, and checking the results statistically. Cases should be alternated. Certain controlled studies which were undertaken and discontinued should be taken up again and as many cases con-

tacted as possible in order to follow the children through adolescence. Such studies would include the New York investigation where most of the children are already entering or are in adolescence.

There is still a great deal to be learned about the BCG vaccine.

If the BCG vaccine is effective, what degree of immunity does it confer? Judging from the results of favorable reports one would conclude that the immunity is not complete as with smallpox, diphtheria, or typhoid inoculations. Although a degree of immunity is indicated, a certain number of tuberculosis deaths may still be expected among vaccinated individuals.

Does the effectiveness last only during the period of tuberculin allergy following inoculation ($1\frac{1}{2}$ to 2 years on the average) as suggested by some authors, or does immunity remain after the loss

of tuberculin allergy, an opinion held by others?

Is separation from a tuberculous source necessary before and after vaccination as claimed by Rosenthal and suggested by the results of the New York study, and if so, can adequate, well controlled foster homes be found?

Why is it that various workers report marked differences in the development of positive tuberculin reactions after vaccination with BCG?

Table 7 summarizes the degree of tuberculin reactivity found in certain studies.

From a public health point of view which would be more efficacious in the eradication of tuberculosis—vaccination with BCG or the separation and hospitalization of all positive sputum cases?

There are so many variables which influence the course of tuberculosis and cause a shift in statistical reports, that

TABLE 7

<i>Author</i>	<i>Type of Vaccination Used</i>	<i>Tuberculin Test Used</i>	<i>Per cent Positive Tuberculin Reactors</i>	<i>Group Vaccinated</i>
Aronson ²	Intradermal 0.1 mg.	PPD	56 1 yr. after vac.	American Indians

renewed and additional research is still necessary before the vaccine can be considered completely efficacious, and be fully accepted as a public health measure.

Is this discrepancy in findings due to the amount and potency of the vaccine used, the method of vaccination, the manner of tuberculin testing, differences in racial groups tested, or the opportunities for contact with human tubercle bacilli?

Further knowledge is also needed concerning the effectiveness of the vaccine in different racial groups, with different degrees of resistance.

Further knowledge is also necessary concerning the stability of potency of the vaccine, and the effectiveness of the vaccine when prepared with different culture media.

It is an accepted fact that although the vaccine has never been known to return to virulence, it does vary in potency, a fact emphasized by Holm.⁹ Means for establishing and fixing the potency should be undertaken.

SUMMARY

1. On the basis of over 5 000 000 inoculations of human beings with BCG vaccine, it can be definitely stated that the vaccine is entirely safe.

2. Numerous favorable reports on the efficacy of BCG vaccine in the prevention of tuberculosis have been published. With very few exceptions these studies have been inadequately controlled.

3. In spite of the fact that results to date are scientifically inconclusive, the consistency of favorable reports would seem to indicate that the vaccine has a certain degree of efficacy.

4. The continuance of BCG research is most essential to determine the degree of its effectiveness.

5. Further knowledge is also needed concerning the duration of immunity; the necessity for re-inoculations; the significance of the tuberculin reaction following BCG vaccination; the efficacy of the vaccine in different racial groups; and the potency and efficacy of the vaccine when prepared with different culture media.

6. Renewed and additional research is still necessary before the vaccine can be considered completely efficacious, and be fully accepted as a general public health measure.

Experience and Lessons from Emergency Maternity and Infant Care*

NATHAN SINAI, DR.P.H., F.A.P.H.A.

*Professor of Public Health and Director, Bureau of Public Health Economics,
University of Michigan, Ann Arbor, Mich.*

RARELY is it possible to point to any single impulse that motivated a broad public health movement. But in 1942 there came out of Fort Lewis, Washington, a plea for help. Peacetime facilities for maternity care were strained beyond their capacity to serve the needs and demands of the wives of members of the armed forces. Logically, the plea was transmitted to the national agency most directly concerned with maternity health, the Children's Bureau. Thus began the movement that resulted in EMIC—Emergency Maternity and Infant Care.

Looking backward from the vantage point of 1946, the evidence is clear that for this problem of the war there was as little preparation as for the many others. Yet, without the drama that attended the solutions of many other problems, the accomplishments in meeting this one stand as a permanent monument to the combined efforts of medicine and public health. Maternity and infant care were the objectives, and maternity and infant care are the accomplishments. The record of almost a million completed maternity cases and over one hundred thousand completed infant cases portrays in cold statistics the

enormous activity of EMIC. EMIC began as a minor effort; it grew to such proportions that it became the chief preoccupation of the Children's Bureau and the maternal and child health divisions in the states and territories. And all this was compressed within the limits of about three years. "Emergency" is a mild word to describe the atmosphere and the driving pressure that attended the expansion of maternity and infant care.

When the movement that later became EMIC started in 1942, certain funds already appropriated under Title V of the Social Security Act were used. These were the maternal and child health funds that could be granted to the states on a basis of need, and without matching the so-called "B" funds. Subsequent developments showed the hopelessness of any assumption that the expenditure in this manner of the total "B" funds, amounting to less than two million dollars, would make even an impression on the problem. As the armed forces increased in numbers, so did this problem assume increasing proportions.

Not until March 18, 1943, did Congress approve the first appropriation for EMIC. It amounted to \$1,200,000. In July an additional \$4,400,000 was approved, and in October the sum granted was \$18,600,000. Thus in the first year of its existence EMIC faced the huge task of expending appropriations involving more than 25 million dollars. On June 28, 1944, Congress approved

* Presented at a Joint Session of the Maternal and Child Health, and the School Health Sections of the American Public Health Association at the Seventy-first Annual Meeting in Cleveland, Ohio, November 12, 1946.

As of September 1, 1945, authorized cases totalled 1,000,000.

As of September 1, 1946, authorized cases totalled 1,100,000.

an appropriation of \$42,800,000 and for the succeeding fiscal year 45 millions. All told, the plea from Fort Lewis gave direction and momentum to an activity that involved the national government, all of the states, all state and many local health departments, a large part of the medical profession and the general hospitals, over one million families, and over 117 million dollars.

All this might imply that EMIC was born and grew to immense stature without friction, criticism, or acute issues. But to many public health administrators who were closely associated with the program during its most intensive period, EMIC was a source of irritation. It is not an unusual state of affairs for public health workers to be dissatisfied with their own work. In this case, however, the dissatisfaction cannot be explained by the healthy urge to attain perfection.

Few will question the background of accomplishment to which the Children's Bureau can point. But despite strong support, in no period of its history, with the exception of those first years when its activities were limited to research, has there been an unqualified professional acceptance of its existence. For the purpose of this discussion the many particular issues of the past are secondary, but the fact that there were conflicts that resulted in submerged and smoldering antagonisms is important.

In much of the war effort that attended the production of ships, shells, planes, tanks, and bombs, the undertakings were without precedent. The lack of preparation and precedent contributed to many mistakes, but these were condoned because it was recognized that, lacking guiding experience, the process of trial and error is the alternative. The only assurance demanded by the American public was that there be no evidence of venality in any action or failure to act.

In contrast to the usual war emer-

gency agencies, EMIC was placed in an entirely different position. The first appropriation by Congress was made upon the assumption, supported by the testimony, that EMIC was not a new program but the expansion of an existing one. Thus, its organization and administration were assigned to an old agency rather than a new one created by the war and, automatically, EMIC became attached to a long series of precedents. With such an urgent need for an accelerated administrative tempo, and without guiding experience, it was certain that mistakes would be made and precedents would be violated.

One of the first casualties among precedents was the established formula of federal-states relations. This is a formula where the diplomatic amenities are of crucial importance. Time must be expended lavishly—time for conferences, time for education, time for extended negotiations and compromises leading to agreement. And one of the most rigid rules of federal-state etiquette is that neither by act nor expression should the representative of a federal agency dominate or attempt to dominate a state agency. Whatever may be the substance of a program, this form must be maintained.

In the atmosphere of war the concept of getting the job done regardless of costs and feelings usually prevails. Getting the job done in EMIC was the primary concern and, no matter how great might be the verbal emphasis upon states' rights, the need for speed and the movement of patients across state lines forced the central administrative agency into a position where the program became federal rather than federal-state, in the usual sense. Ordinarily three months would be required to complete arrangements for preliminary discussions; in this instance and within the same period the plans of thirty-eight states had been approved by the Children's Bureau. Without a detailed

master plan that served as a blueprint for the state plans there would have been months of delaying negotiations.

The need for speed brought its predictable responses. Regulations were adopted covering the details of administration, and new experiences resulted in changes in regulations. Those affected by the changes felt harassed but this, in itself, did not differ greatly from other war efforts. Where EMIC differed was in the tendency of those concerned with administration to view the program with one eye on the immediate task and one eye on future policy. The interesting feature of the phenomenon is that both the Children's Bureau and the state health departments were concerned over the possible effects of EMIC on future programs. With an eye to the future, what state health departments saw and interpreted as federal domination was disturbing to them.

The Children's Bureau also observed in EMIC some possible post-war difficulties. Getting the job done was the primary ask, but getting it done regardless of costs was another matter. As a cost of war, a fee of \$50 or \$150 for maternity care is relatively unimportant. But if the fee is regarded as a possible pattern of post-war costs of maternity care it becomes extremely important. Hence, in this aspect and many others the actions of the Bureau were more in accord with a peacetime outlook than a wartime psychology.

These are some of the causes that are discernible in criticisms of EMIC. There is one, however, that perhaps outweighs all of those mentioned. EMIC was launched in a period when there was great debate on the subject of a national health plan. In a short time it became apparent that EMIC was a national health plan. Those who regard EMIC as a complete preview give too little attention to its emergency characteristic—the need for speed. They say, "This is it" and assume that what happened

in EMIC, be it good or bad, will happen in any national health plan. The assumption gives little credit to the process of learning by trial, error, and experience. If EMIC is regarded as an administrative laboratory, the lessons in it are of incalculable value. They may be applied to a wide variety of situations—national health plans, state health plans, and others. Whether they are applied by national or, particularly, by state and local health departments is a question that cannot be answered now because the future administrative rôle of these departments remains in doubt. But, whatever the agency, the lessons are pertinent.

EMIC demonstrated that the most crucial period in the existence of any large scale plan is that period *before* the distribution of any service begins. While this is no new principle of administration, what EMIC contributed is a much more tangible concept of how much time is needed and how the time must be used. Between the decision to adopt a plan and the delivery of services, a period of at least a year should elapse. Without such a "get-ready" period the plan will duplicate much of the adverse experience of EMIC.

EMIC began without sufficient trained personnel in the Children's Bureau and without sufficient trained personnel in the states. It is in this light that the amazing accomplishments throughout the country must be viewed. But one such demonstration is more than enough to show the pressing need for administrative personnel and to indicate how intensively a training period of a year must be used. Intensive training introduces another responsibility, the development of training facilities and teaching personnel. If this responsibility is not met by schools of public health, as a part of their own "get-ready" period, a chaotic educational effort will result.

The training of personnel and the

testing and perfection of administrative mechanisms are only parts of the work during the preparatory year. A far-reaching program of education is vital to the future success of the health plan. If the Children's Bureau and the state health departments had had a year to confer with and acquaint the medical profession, hospitals, and potential recipients of service with the details of EMIC, how much misunderstanding would have been prevented! And how much would have been learned about the applicability of proposed rules and regulations!

Probably the most outstanding contribution of EMIC to the field of health administration is related to hospitals and hospitalization. The contribution, based upon previous experience with the services for crippled children, involves hospital standards as well as hospital costs. There is a striking agreement among hospital administrators that the EMIC formula for hospital payment, which is based upon the costs of hospital care, focused attention upon a subject that should have been considered long ago. And the EMIC standards for hospital facilities threw new light on the hospital needs of the nation.

It was by one of those significant circumstances that, through EMIC, state departments of health became associated with problems of general hospital administration at a fortunate time.

It was after the EMIC program started that there appeared on the agenda of Congress the Hill-Burton proposal to grant federal funds for hospital construction. In August, 1946, Senate Bill 191 became Public Law 725. Under this law the combined federal and state expenditures for hospital and health center construction may approximate one billion dollars in five years. The federal administrative agency is the U. S. Public Health Service, and any state wishing to avail itself of federal

funds must meet these two requirements, among others.

1. A single agency must be designated to plan and, within the framework of federal rules, carry out an approved construction program.

2. Minimum standards for the maintenance and operation of hospitals that receive federal aid must be adopted.

The most logical single agency in a state is the health department. Because of the EMIC program, all of the state health departments have gained at least some experience that should be valuable in this new development. Of course, the most fortunate states are those with a background of experience acquired through the enforcement of hospital licensing laws.

If any regret is in order it lies in the failure of the states to prepare more adequately for the administration of Public Law 725. But this much appears to be certain: As direct payments to hospitals by private patients decrease and payments from public agencies increase, the responsibility of determining what are reasonable charges for services in each hospital will fall upon the "single state agency." Hence, for those departments that would remain aloof from the controversial issues of medical and hospital administration, designation as the single state agency should be avoided.

EMIC demonstrated also how delicate is the subject of medical specialization. At first glance the designation of specialists in a national or state health plan appears to be disarmingly simple. The administrator of such a plan, aided by an advisory body, is charged with the responsibility of preparing and publishing a list of those who are qualified. And the list is expected to be a duplicate of the names approved by American Specialty Boards.

The first reaction to the proposal that a public administrative agency designate specialists comes from the medical pro-

fession. The charge is made that the function is outside the province of public administration and is an unwarranted encroachment on the prerogatives of the profession. The issue appears to be one of those for which people fight and die and their friends wonder why. Up to this point the controversy seems to revolve around the issue of what agency will publish names from a list already published.

In EMIC the state agencies accepting the profession's declaration of prerogatives placed the responsibilities of designation upon the profession in the states and local areas. It was then that the realities of the situation began to assert themselves and simplicities became complexities.

The designation of specialists becomes an important matter when it is proposed that, for the same service, a specialist receive a higher fee than that of the non-specialist. In EMIC the difference amounted to 50 per cent. Higher fees for those with specialized training is generally accepted as a part of the tradition of private practice. But it has never been formalized as it must be if it becomes an accepted policy in any system of organized payment.

The obstacle to the designation of specialists, and, therefore, to the payment of higher fees, is seen in the informality of specialization in the United States. There are fifteen American Specialty Boards and the standard of each one is high, but this does not mean that a physician who specializes must be approved by the particular Board. Thus, in the same community there may be an approved specialist, another physician not approved but nonetheless specializing, and a third physician not approved but specializing to the extent of 50 per cent of his practice. Are all to be given approval and, if so, what standards should replace those of the American Specialty Boards? It was in the face of such realities that the pre-

rogative of designating specialists was pushed into the background. The whole experience has had its sobering effects and EMIC has demonstrated the need of a new approach to the problems of payment and their relation to the specialization of practice. The problems are inherent regardless of whether a national or state plan under government or private auspices is being considered.

One of the phenomena of national state and local administration is the movement of criticism from the bottom to the top. Inflexible central administration in the state can be as uncompromising as this type of administration for the nation. In a state where the severe denunciations of central administration by the Children's Bureau are most pronounced it is not unusual to hear local administrators make the same criticism of rigid central administration in the state. The subject warrants attention because in too many cases it is assumed that the problems faced by EMIC would be solved with ease if the state, rather than the nation, were the basic unit of administrative authority. The assumption and the evidence are not in accord.

Considering the administrative problems that faced EMIC, it is very doubtful that they would be less acute if a like program or an expanded health program were limited to a state. Almost any state, and certainly any populous state, would be forced to adopt either a flat fee schedule regardless of geographic area or the qualification of the physician, or a fee schedule that would vary according to these two factors. As stated, the policy of EMIC was to vary the fees according to qualifications but not according to rural or urban practice. As a result, the basic obstetrical fee of \$50 met with a fairly favorable response among rural physicians. However, it is much less likely that rural physicians would look with favor on a higher fee

for a service rendered by a general practitioner in an arbitrarily defined urban community. In the public mind, higher fees are usually associated with higher quality. It is fairly certain, therefore, that pressure would be exerted by the profession in the smaller communities for a flat fee at the level of urban payment.

What has been said also about the designation of specialists would not become a less acute problem under a state system or a grant-in-aid program. This statement is not made in support of a federal program; it is intended to emphasize the fact that complex problems do not suddenly simplify merely because administrative authority is concentrated in a state. Nor do they simplify when the authority is voluntary rather than governmental. With respect to the problems described, the voluntary plans have contributed little.

One final example of lessons from EMIC will be presented; many others will be included in a forthcoming report of a field study.* The example involves the quality of service and the methods that might be used to improve it. The EMIC program raises the old question of whether the chief dependence should be placed upon education or regulation. And the answer appears to be "both." Regulation is necessary for the improvement of facilities; with respect to medical service it is a doubtful procedure in a long-range program. Under the pressure of time, a divided fee for obstetrical care, as a way to assure or increase antepartum and postpartum care, may be justified. But in a continuing program improved services based upon sound public and professional educational efforts generate less antagonism and create fewer administrative problems. As a sidelight upon the future of ob-

stetrical care in the United States, it is significant that hospital facilities have been improved and, further, that those expectant mothers who have had an experience with a high quality of care expect that type of service and are critical unless it is received.

The many administrative lessons in EMIC will be valuable or valueless according to the outlook of public health administrators. The present period is one of indecision in spite of the Official Statement adopted by the American Public Health Association in 1944.* As long as the indecision persists, the type of experience provided by EMIC will be viewed negatively, *i.e.*, adverse experience will be emphasized as reasons why health departments should "stick to their knitting," enlarging, perhaps, but not changing the forms of their work. If this describes the position of state and local health departments it is quite understandable that EMIC should be viewed as an unwanted burden forced upon them by the war. Whether the position is a realistic one and in the interest of adequate health administration is another matter.

Somewhere in the structure of state administration there must be preparation for medical and hospital administration. One event has already occurred and certain responsibilities of hospital administration are being placed upon state health departments. But there are other events involving medical administration that are already over the horizon. It is a safe prediction that legislation for disability compensation will be enacted in many states, and good administration requires that an official agency issue the necessary certificates of incapacity. Will state health departments take the position that this is a task that is to be performed by departments of unemployment compensation?

* To be published by the Bureau of Public Health Research of the School of Public Health, University of Michigan. The study was made possible through grants of funds by the Field Foundation and the New York Foundation.

* Medical Care in a National Health Program. *A.J.P.H.*, 34, 12:1252 (Dec.), 1944.

If so, departments of unemployment compensation must develop their own system of state and local medical administration. If disability compensation, like workmen's compensation in the past, expands to include medical service for those disabled, it is unlikely that this type of medical administration will be relinquished to state health departments.

It is useless to adopt resolutions of protest against the multiplicity of health or medical administrative agencies without taking positive steps to prevent pre-

dictable duplications. Also on the horizon of health legislation are many other state and national proposals for medical and hospital care. Whether attention be centered upon a bill sponsored by Senator Wagner or Senator Pepper or Senator Taft, the characteristic that is common to all proposals is the complexity of administration. It was to the processes of administration that EMIC made distinct contributions; the lessons of EMIC assume greater importance when the interpretations are made in the light of impending events.

AMERICAN PUBLIC HEALTH ASSOCIATION

Next Steps in Industrial Hygiene Research*

PAUL A. NEAL, M.D., F.A.P.H.A.

Medical Director, Laboratory of Physical Biology, National Institute of Health, Bethesda, Md.

THE field of industrial hygiene research is as wide as the scope of human activity. Protection of human beings from hazards of their occupational environment exacts research demands which are highly diversified and extremely complex. This complexity is emphasized because the work is not related to a single disease entity, with specific manifestations, causes and cures. It is further complicated because the industrial scene is never static.

Just after the turn of the century it became increasingly apparent to industrialized countries that it was poor social and business economy to subject workers to avoidable industrial hazards. Following each war there has been a wider recognition of this utilitarian value of industrial hygiene research.

Industrial hygiene research is thus so unlimited in scope that one is in a dilemma even when he tries to draw a distinction between industrial hygiene research and general public health research, because the former covers many phases with regard to the working environment which the latter covers with reference to the general population.

In general, at present industrial hygiene research concerns itself essentially with the effect of different environmental factors on the normal

worker, and may be divided into the following categories:

1. Effect of physical factors, such as abnormal temperatures, humidities, and pressures, noise, vibrations, etc., on the worker
2. Effect of posture, fatigue, rest pauses, physical fitness, infectious agents and susceptibility to disease, on the organic function of the worker
3. Effect of gases, vapors, fumes, and dust on the worker
4. Effect of radiations and nuclear particles on the worker

ENVIRONMENTAL PHYSIOLOGY

Numbers 1 and 2 above are usually discussed under the general term of environmental physiology.

The extent to which research has been undertaken in the United States on environmental physiology has never been on a par with its importance. It is odd that a country with industry as technologically advanced as in the United States has not devoted more effort to this field of research. The operation now and in the future of complex machinery and technical processes demands of the industrial worker a high level of functional capacity and training. For example, with the approach of a new era in air transport, aircraft engineers and designers are rapidly realizing that unless human requirements and limitations are carefully assessed, and balanced, aircraft impossible for human occupancy and control with any acceptable degree of safety may be produced. Similar con-

* Presented before the Industrial Hygiene Section of the American Public Health Association at the Seventh Annual Meeting in Cleveland, Ohio, November 12, 1946.

siderations may be applied successfully throughout industry in the adaptation of the machine to suit men rather than the adaptation of men to suit machines.

Present physiological knowledge does not allow the full statement of man's capabilities. The physiological approach to these problems involves the study of the range of human function. For example, we must have information on what a particular task demands of the worker's motor system, sensory system, and capability for adaptation and acclimatization. This requires a knowledge of the physiological limits of these several functions. Obviously, this body of knowledge is far from complete and the establishment of such fact is the proper function of physiological research.

The integrated details of such physiological approaches border on consideration of comfort and morale, and it is probable that these factors must be studied in relation to the worker's task. For example, recent work has indicated that adjustment of industrial processes to "comfort of workers" results in a significant increase in work output. The lack of mental stress under these conditions is a morale factor of great importance in labor management relations.

TOXICOLOGY

At present toxicology may be defined as the *unfavorable* effect of drugs and chemicals on the *normal* organism in contrast to pharmacology which may be defined as the *favorable* effect of drugs and chemicals on the *diseased* organism. The interpretation of the word toxicology has been gradually changing over the past years. At one time it was devoted solely to the analysis of the stomach contents of a person who had been suspected of being poisoned by some chemical.

Later, as more information was obtained concerning the gross action of

many substances (such as corrosive agents), the means for neutralizing or combating the immediate effects of such agents became a part of "toxicology." Later still, the term came to include the effects of toxic chemicals on workers in industry, the toxicological information being obtained from observations by a single individual of the industrial environment on the workers who were obviously ill.

Later, field epidemiological studies were undertaken in which the environmental exposures were quantified and physical examinations were performed on the workers. It was thought that by the study of the data collected, the toxicity of the substances in question could be determined and engineering and medical control procedures defined. It is apparent that laboratory research had to precede such studies in order to develop methods for quantifying the environmental exposures as well as to define the early symptoms and signs of such exposures on the individual. The control procedures developed by such laboratory and field studies in the past decades are now generally accepted and, with few exceptions, the working environment has been remarkably improved. For example, severe lead poisoning in printers and painters is relatively rare, and mercury poisoning in hatters is no longer a menace.

At present, industry and labor demand that the toxicity and potential dangers of new chemicals, or old chemicals used in new processes, be defined, and that safe medical and engineering control procedures be available before any workers are exposed. Safe control procedures are now defined as methods that will prevent not only definite illness, but also will prevent minor physiological impairments. Therefore, in the laboratory evaluation of toxic agents or harmful environmental situations, it no longer suffices to produce acute injury in the experimental

animal and then simply to tabulate mortality or gross changes. It appears imperative that in the future toxicological research should concern itself much more than heretofore with detailed studies of certain chemicals on the physiological and biochemical response of the organism, and that such effects as may be found be followed in series of homologous substances in order to discover the mechanism of action of such chemicals and the laws which control such effects. It is obvious that such detailed research cannot be performed by a single individual, but that it requires the teamwork of a number of disciplines, as pharmacologists, physiologists, biochemists, cytologists, enzymologists, and biophysicists. Such investigations are not only concerned with the effect of such chemicals on organ function, as heart action, liver and kidney function, but it has also to delve into the response of individual cells and enzymes, which includes the carcinogenicity and allergic potentialities of such chemicals.

The toxicologist must determine just what the toxic agent does to the body's economy. This means finding out how it affects the metabolism of normal body constituents, and how it affects nervous and hormonal mechanisms and the function of the various enzyme systems. In addition, he must determine exactly and in minute detail how the body reacts to the foreign agent. This means finding out how the agent is metabolized, what its end products are, and where these chemical transformations take place. Real progress in toxicology depends on carrying out such fundamental investigations. As an example, one may cite the studies done in Great Britain and in the United States on lewisite. It was found that this toxic gas had a great affinity for certain sulfur groups in protein, the —SH or sulfhydryl groups. Various vital enzymes must have these sulfhydryl

groups intact, else they become inactivated. These enzymes could be protected, and the whole organism could be protected, by means of several synthetic compounds containing two sulfhydryl linkages in the molecule. One of these is BAL, whose usefulness in arsenical, as well as mercury poisoning, is becoming well known.

As another example of a thorough toxicological investigation the studies on diisopropyl fluorophosphate (DFP) may be mentioned. The most recent techniques in enzyme chemistry, pharmacology, physiology, and biophysics were used in evaluating this toxic agent in several laboratories. It was found that DFP irreversibly destroys the enzyme cholinesterase. This effect might be desirable in certain conditions like glaucoma, and clinical trials have been started. If the tests prove successful, it would provide an interesting situation, where fundamental studies of a toxic agent have disclosed therapeutically useful properties.

Unfortunately, the role of —SH groups described above is a rather isolated island of knowledge surrounded by mystery still too deep regarding the mode of action of numerous other substances which do *not* appear to exert their effects by this route. In fact, even the sulfhydryl picture has many gaps requiring further investigation, such as how the enzyme effects can be correlated with the details of pathology and the clinical course of poisoning by the agents studied. As a result, toxicology has come to depend more heavily than ever on fundamental findings concerning the properties of living matter. As the frontiers of knowledge concerning the *normal* cell are advanced the toxicologist will be given new tools for application to his particular interests. In a sense the appellation "toxicology" has lost much of its original definiteness —and, just as industrial hygiene has

come to involve essentially preventive medicine and public health in all their aspects, toxicology can be said to involve pharmacology, physiology, biochemistry and even biophysics in addition to pathology and clinical medicine.

Over the last generation, sanitary engineers have provided us with safe milk and safe drinking water. Unsafe air is probably just as much a hazard to the health of society as unsafe food and water. It is going to be a problem of the immediate future to establish satisfactory safety standards for the air we breathe and to see that these standards are enforced. These standards cannot be properly defined until fundamental research has provided them with a sound basis of fact any more than proper standards for milk could have been set before the pertinent bacteriology of the typhoid and tuberculous organism had been established. Foul air is not simply smoke-laden air or air contaminated with toxic dusts and gases in a factory. Upper respiratory diseases, including the "bad cold," cause several times as much sickness absenteeism as do occupational diseases. At present, we know that "bad colds" are contagious and that in their transmission the air we breathe plays an important part, but it remains for future research to determine how important this part is and its mechanism of transmission.

There has been work in the past—a great deal of work—done in the study of air pollution, but new research tools are steadily being developed which can be applied to its unsolved problems, and it is essential that we should continuously reconsider these problems in the light of these new tools and utilize them for what they can contribute. For example, a large proportion of the toxic and infectious particles in contaminated air are too small to be seen with the ordinary microscope. They all fall, however, within the range of the electron

microscope which is directly revealing particles of molecular size. With it, we can then begin to study these extremely minute air-borne particles which by reason of their small size can gain entrance to the alveolar spaces of the lungs.

RADIATION BIOLOGY

The recent developments in atomic energy have opened up possibilities for biological research that are difficult to overestimate. However, the potential health hazards incident to the industrial and scientific development of nuclear energy are great, especially when one realizes that one of the major obstacles to the use of such energy is the protection of human beings from radiations. In addition, the development of improved electro-nuclear devices, such as synchrotrons, accelerators, and frequency modulated cyclotrons pose new health hazards as well as provide new tools for biological research. The continued expansion of the industrial use of radiations of ever increasing intensity, such as 2 million volt x-ray equipment for the study of castings, demands fundamental biological research for the protection of workers.

The preceding statements are expressions of the fact that the Public Health Service has become increasingly cognizant over the past few years of its overall responsibilities in the matter of employing these new concepts in its research in cancer, gerontology, infectious diseases, physiology and toxicology, etc., as well as to work out procedures for the protection of the individual.

The public health aspects of these recent developments in nuclear energy may be considered under two general headings: (1) health physics or methods for the prevention of injury from radiations, and (2) the use of these new tools in biological research.

With regard to the protection of the individual, it is imperative that the in-

formation at present available on medical and engineering control procedures be more definitely formulated and more generally distributed. This must be accompanied by the training of personnel of various disciplines in order that an integrated application of this knowledge may be possible.

The use of these new tools in developmental and fundamental research in industrial hygiene offers great promise. At the present time, it appears that the greatest contribution which the recent developments in nuclear energy can offer to toxicological and environmental physiological research is in the field of radioactive tracers. A better understanding of the hazards involved will demand a continuation of the study of practical problems in order that safe control procedures may be established.

For many years the National Institute of Health has been conducting fundamental and applied research on the biological effects of low energy radiations, especially ultra-violet, and more recently on high energy radiations—x-ray, gamma and neutrons. As a natural sequence, the National Institute of Health has become associated with the Clinton Laboratories, operated by the Monsanto Chemical Company. This

coöperative undertaking has resulted in the establishment of a Biological Research Division at Clinton Laboratories. Dr. Alexander Hollaender, principal biophysicist of the National Institute of Health, will direct the program as head biophysicist assigned to the Clinton Laboratories. He will be associated with Dr. Eugene P. Wigner, Research Director of the Laboratories. This coöperative undertaking will allow the National Institute of Health to utilize these new tools, particularly high energy radiations and radioactive isotopes, in their present and future research programs, as well as to train personnel in the increasingly important field of personnel protection.

A joint program is being developed by the National Bureau of Standards and National Institute of Health which would establish in the Washington area a radiation laboratory, including pile facilities for fundamental research in the chemical, physical, and biological aspects of high energy radiations.

Dr. Edward U. Condon and Dr. R. E. Dyer, Directors, respectively, of the National Bureau of Standards and the National Institute of Health, will present preliminary plans to the Atomic Energy Commission as soon as possible.

The Present Status of Vaccination Against Influenza*

PROPHYLACTIC EFFECT OF VACCINE

THE evidence for protective effect of vaccination against influenza with combined A and B virus vaccine resides largely in studies carried out by the Commission on Influenza, Army Epidemiological Board. In the winter of 1943-1944 an evaluation of the effect of vaccination against influenza A was made. In this study (*Am. J. Hyg.*, July, 1945) which was carried out in Army Specialized Training Program units in different universities throughout the United States, approximately 6,250 individuals received vaccine, and a similar number received control inoculations. During the epidemic of influenza A which shortly ensued, the incidence of clinical influenza in the vaccinated group was 2.2 per cent and in the control group 7.1 per cent. In all but one group the trends were similar and in some instances the ratio in favor of vaccinated individuals was considerably higher.

It is evident that complete protection was not obtained, but it must also be recognized that the 1943 studies were carried out with the first preparations of vaccine made on a large scale.

In 1945 observations on the effect of vaccination against epidemic influenza B were possible by virtue of the Army program of general vaccination. At the University of Michigan there were 600 vaccinated men in the Army unit while in a unit of another service there were 1,100 unvaccinated men. Both groups

were cared for at the University Student Health Service under similar regulations for admission to hospital. During the epidemic period of November and December the incidence of admissions in the unvaccinated group was 9.9 per cent and from the vaccinated group 1.1 per cent (*J.A.M.A.*, May 25, 1946). At Yale University conditions were almost identical as to numbers and in the character of the observations. There the incidence of influenza in the unvaccinated group was 12.5 per cent and in the vaccinated group 0.5 per cent (*Am. J. Hyg.*, Jan., 1947). While neither of these studies was alternately arranged as was the one against influenza A, the results seem clear.

Evidence obtained in the 1943 studies indicates that the effect of the vaccine appears in about one week.

DURATION OF EFFECT

The duration of protective effect is not established. In all studies referred to, vaccination had been conducted only a few weeks before the onset of the epidemic. Certain observations made in institutions (*J. Exper. Med.*, Oct. 1944, *Am. J. Hyg.*, Nov. 1945) indicate that as long as 1 year after vaccination its influence was detectable, statistically, in reduced incidence of disease among vaccinated individuals, although it is by no means certain that with present procedures a satisfactory degree of resistance can be maintained for so long a period. The data indicate, however, that resistance is not limited to a period of 4 to 6 weeks, but more study is required to define the effective period.

Indirect evidence as to the effect of vaccination is seen in the stimulation

* Report of the Study Committee on Influenza Vaccination of the Subcommittee on Evaluation of Administrative Practices, Committee on Administrative Practice, American Public Health Association, April, 1947.

of antibodies and their persistence. In vaccinated groups the mean antibody response reaches its height about 2 weeks after the inoculation of the vaccine, declines approximately one-third in 4 to 5 months, and to about one-half its peak level in 1 year, although it still remains well above the prevaccination level. If, as is generally assumed, there is a correlation between the height of antibody level and resistance, these data offer support to the interpretation of an extended influence of vaccination. It cannot be accepted at present, however, that the duration of resistance is parallel to the persistence of antibody levels. Individual variation occurs and a certain proportion of individuals fail to obtain a satisfactory response. Moreover, certain individuals tend to lose antibody more rapidly than the majority. Where doses of reasonable amount are used there is little evidence that repeated inoculations at short intervals afford any advantage.

SPECIFICITY OF EFFECT

On the basis of present knowledge, influenza virus vaccine appears to have an effect of a rather specific nature against infection by influenza A and influenza B. There is no evidence that vaccine influences the incidence of common colds and other unidentified respiratory infections. Nor is the effect of vaccine as now constituted against all the possible variant strains known. There is no satisfactory evidence of protection against such an epidemic as that of 1918.

REACTIONS TO VACCINE

In a proportion of individuals influenza virus vaccine given subcutaneously elicits a reaction similar to a mild reaction to typhoid vaccine. There is commonly redness and tenderness for a few days at the site of inoculation; in recent experience involving many thousand inoculations, less than 1 per

cent of those receiving the vaccine were observed to have fever. This is usually of no more than 24 hours' duration, and the aches and discomfort which accompany fever ordinarily can be controlled by the use of mild analgesics. Evidence points to the fact that the frequency of this form of reaction is related to the amount of virus present in the vaccine rather than to extraneous egg materials. The number of reactions with purified material increases as the virus content of the inoculum increases. It is suggested that material which has aged gives fewer reactions than freshly prepared material. Experience to date indicates that children are more prone to sharp febrile reactions than are adults. It might be suggested that, for children under 5 years of age, 0.1 to 0.3 ml. be given; from 5 to 10 years, 0.5 ml.; above 10 years of age the full dose, 1.0 ml.

No jaundice or central nervous system disturbances have been seen to follow influenza vaccination.

Practically all preparations at present being recommended are prepared from the allantoic fluid of the developing chick, which ordinarily is not a highly sensitizing material. It should not contain yolk, membrane, or egg white, except as this may accidentally enter in the course of production. Because of the source of material, however, the possibility of anaphylactic reactions must be kept in mind. In the large number of individuals who have been inoculated to date, such reactions have been extremely rare. Nevertheless, because they have occurred, it is imperative that careful histories be taken to determine the presence of asthma or urticarial sensitivities to chickens and eggs. Epinephrine and other anti-spasmodics should be readily available. It has been suggested that all individuals should receive skin tests before receiving vaccine. This seems unnecessary if other precautions are

observed. Vaccine has been given without disturbance to a good proportion of individuals who give histories of mild or moderate allergy to eggs, but skin tests should be done in these instances before vaccine is administered. If the history is marked or if there is any hesitancy about the decision, vaccine should not be given.

Data obtained up to the present time do not suggest that vaccine has a prominent sensitizing effect. This statement is based upon experience in individuals who have been vaccinated a second or third time. Further observation is required to determine whether sensitization will increase in frequency with additional inoculations.

The question has been asked recently concerning the administration of vaccine to pregnant women. There are no obvious contraindications other than those suggested above.

PREPARATION OF VACCINE

Most of the clinical evaluation in Army groups was made with vaccine material absorbed to and eluted from embryonic chicken erythrocytes. Since that time several producers of influenza vaccine have sought to eliminate unnecessary materials in the egg fluids. Various biological houses have been developing preparations by precipitation, centrifugation, etc. These products are licensed by the National Institute of Health and are required to pass similar potency tests for release. If they present adequate virus content and stability without disproportionate pyrogenic effect, they are probably prophylactically effective. Technical development of vaccine has not reached the final state and it seems unwise at the moment to seek minimal effective dosage.

GENERAL APPLICATION

Influenza A has occurred in epidemic form at intervals of 2 to 3 years; in-

fluenza B, at intervals of 4 to 5 years. It was anticipated on the basis of the preceding experience that an epidemic of influenza A would occur in the winter of 1946-1947; blustery, irregular outbreaks of the disease were identified in the spring. The time of the recurrences cannot, however, be rigidly predicted. Although the epidemics have been widespread, the clinical disease has been generally mild and of comparatively low incidence. The resistance induced by vaccination is not known to persist effectively from one season of prevalent respiratory infections to another, and the expense of the vaccination must be considered.

In view of these considerations, a recommendation for general employment of influenza vaccine by health departments is not warranted administratively at the present time.

On the other hand, in certain groups the prevention of influenza even in a mild form is to be sought. These comprise older individuals in whom the case fatality tends to be high, the debilitated or others to whom infection presents undue risk, industrial groups and essential public service personnel in whom even temporary incapacity constitutes a serious problem, and institutional groups or university students for whom facilities for care when sick are limited. The highest incidence of the disease is in children, but the mortality is extremely low.

Under these conditions the question of when vaccination should be given is open to discussion. For a large population, geographically widespread, it seems possible to gain full advantage only if vaccination is conducted in advance of the appearance of influenza A or B. On the other hand, in institutions or closely knit industrial groups, vaccination might well be withheld until evidence is obtained that epidemic influenza is occurring. However, the speed at which the disease disperses is

so great, and since the interval between inoculation and effect is at least a week, there is difficulty in carrying out the program in time to secure its advantages.

Milwaukee's Hall of Fame

Milwaukee has an annual Hall of Health made up of a health day forum and exhibits, and an additional program prepared by the Medical Society of Milwaukee County and its Women's Auxiliary. Exhibits are prepared by health and social agencies while the City Council provides the auditorium halls.

The 1947 Hall of Health was held in May. Among the public exhibits were three by the U. S. Public Health Service on early detection and treatment of tuberculosis on a mass scale, industrial hygiene and early detection in cancer control, respectively; one by the Army Medical Corps on "dynamic convalescence"; and several by the American Medical Association on the history of American medicine, hay fever, and pneumonia; and one by the Army Air Force on protection of crews and passengers in high altitude flying.

The outstanding feature of the 1947 exhibit was provided by the Milwaukee chapter of the Wisconsin Society of Professional Engineers. This is a large

oil painting, "Engineering and Health," by George E. New, Ph.D., a well known artist. The painting, seven by four feet, depicts the engineering profession's contribution to better health. The four corners symbolize the areas in which engineering has made its greatest contribution. The central figure holds a flaming torch to symbolize engineering lighting the way.

The placard accompanying the painting says in part, "Eye-saving illumination, pure water, air-conditioning, heating and refrigeration—these products of engineering skill are a part of our daily living. Engineering rears great buildings, safe and comfortable for us to dwell and work in. Through irrigation it increases the fruitfulness of our life-giving soil. It provides swift transportation and communication to bring healing aid. It makes the instruments to find and fight disease. Men in all branches of engineering turn the discoveries of science into practical use for the service of the people."

Food Values of Dairy Products as Affected by Methods of Handling in Production, Distribution, and Use*

Riboflavin, Thiamin, Vitamin A

Food and Nutrition Section

THE Committee on Milk and Dairy Products has surveyed recent research studies in an attempt to determine the effect of many factors operating between production and consumption, which may influence the ultimate nutritive values of dairy products.

Obviously, it was impossible to draw general conclusions regarding food values when several dairy products were considered and many possible affecting factors were analyzed. The only course for the committee to take was to limit the scope of the study to a consideration of a few nutrients. The following report, therefore, is based on recent literature (1940-1946) pertaining chiefly to the nutrients: riboflavin, thiamin, and vitamin A.

Each of the dairy products—milk, butter, cheese, and ice cream—is considered here from the standpoint of factors which may affect their riboflavin, thiamin, and vitamin A values. Milk as the basic product from which all dairy foods are made is considered first, from production on the farm to use in the home.

RIBOFLAVIN IN MILK

The fact that milk is an excellent source of riboflavin makes it important

to know what factors in production and handling of milk affect its riboflavin content and which of these factors can be controlled to assure a maximum concentration of riboflavin in the milk. The feed of the cow is naturally a first consideration.

Ration of the Cow—The literature indicates that the riboflavin content of milk *can* be influenced by the feed of the cow. However, increasing the riboflavin intake of the cow by 30 to 50 per cent, as reported in one study, caused only a temporary increase in the concentration of the riboflavin in milk. In the same study, a good winter ration maintained milk riboflavin at pasture levels.¹ According to another report, cows transferred from winter rations to young green pasture gave *more* milk but with slightly lower concentration of riboflavin.² Other investigators have also shown the inverse relationship between milk yield and riboflavin content of milk. In addition, they have demonstrated that the concentration of riboflavin in milk can be increased when a dry ration is supplemented with a silage.³

In spite of these apparently conflicting observations, it appears likely that milk, as produced under standardized

* Report of the Committee on Milk and Dairy Products.
COMMITTEE ON MILK AND DAIRY PRODUCTS

Organized 1929 Published reports Year Books 1930-1931, 1931-1932, 1932-1933, 1933-1934, 1934-1935, 1935-1936, 1936-1937, 1937-1938, 1938-1939, 1939-1940, 1940-1941, 1941-1942.

feeding and management conditions existing on modern dairy farms, is relatively uniform in riboflavin content the year around.⁴ The fact that some synthesis of riboflavin in the bovine rumen has been demonstrated on specified experimental rations^{5, 6} may help to explain the relatively stable riboflavin content of milk.

Light and Heat—The action of heat alone does not influence the riboflavin content of milk. However, heat and light acting together, may be responsible for considerable loss. The studies reporting such losses vary greatly in plan and procedure, a fact which makes it difficult to compare their results. In general, milk exposed either to direct sunlight out-of-doors or to relatively strong daylight indoors loses riboflavin, the amount of loss depending on the directness and strength of the light, the length of time of exposure, and the temperature and pH of the milk. Strong light, long exposure, warm temperature, and increase in alkalinity all contribute to losses of riboflavin. Typical studies are reviewed briefly.

In one study, milk in pint bottles, exposed to the direct sun (between mid-morning and midafternoon) on an open porch, lost from 28 to 72 per cent of its original riboflavin content, the time of exposure ranging from 30 minutes to 3½ hours. The atmospheric temperature varied from 60 to 72° F. Control samples of milk, kept in a dark room for 24 hours or in a refrigerator for 7 days, suffered no loss of riboflavin.⁷ Similar findings are reported by other investigators.⁸⁻¹¹

Reports also describe research designed to answer questions covering the effect of sunlight on different types of milk, on milk in different kinds and sizes of containers, and under various other conditions of practical importance.

In general, it was found that there was less destruction of riboflavin when homogenized milk (27.6 per cent) was

exposed to sunlight from 1 to 2 hours than when pasteurized (35.4 per cent) or raw milk (40.1 per cent) was subjected to the same treatment. Destruction of riboflavin in clear glass bottles ranged from 9 to 77.5 per cent (the amount related directly to time and temperature); in brown bottles from 0.6 to 5.6 per cent; in paper bottles from 0.6 to 16.9 per cent.¹¹

A recently reported study combines an investigation of theoretical losses of riboflavin with observations of ordinary practices in handling milk, which may influence such losses.¹² The authors agree that losses *can* be severe but that the consumer takes greater precautions in the care of milk than is ordinarily assumed. They found, for example, that 70 per cent of all milk delivered on retail routes was removed from the doorstep or was protected from light in some manner (often by a covered receptacle) within 5 minutes after delivery. As a result, the milk lost almost no riboflavin. Only 3.3 per cent of the customers left milk exposed on doorsteps for more than 2½ hours. The authors indicate that a calculated loss of 3.25 per cent of riboflavin, after milk is delivered to the customer's doorstep, is a high estimate.¹²

Other interesting observations: The smaller the container of milk, the greater the destruction of riboflavin in a given time. Also, as would be expected, wooden cases for holding bottles protect milk from riboflavin losses more effectively than do wire cases; milk stored at the back of the delivery truck, away from light and warmth, has the advantage over milk placed near the door.

Losses enroute are negligible in general, except where milk is on a route for 5 hours or more.¹²

Another group of investigators found that chocolate milks lost riboflavin very slowly when exposed to sunlight. The average loss of riboflavin after 4 hours, for five different brands of chocolate

milk, was about 12 per cent as compared to a loss of 80 per cent for white milk.¹³

Proper care of milk in the home is important if the riboflavin content of milk is to be protected. In one study, conducted in a well lighted room, milk placed 5 feet from a window lost from 16 to 99 per cent of its riboflavin when held at 100° C. (boiling) for varying periods from 5 minutes to 1 hour and as the pH increased from 3 to 6.5.¹⁴ When milk was allowed to simmer for 30 minutes in a covered glass pan, in a covered aluminum pan, and in an uncovered aluminum pan, the losses of riboflavin were 8 to 11 per cent; 1.1 per cent; and 10 to 12 per cent, respectively.¹¹ When quart bottles of milk were allowed to stand for 2 forenoon hours on a table in a light kitchen with east exposure, but not in direct sunlight, 3.2 per cent of the riboflavin was lost during the first trial and 4 per cent during the second trial.¹²

The practical application of these findings is obvious. For the most part, the properly informed consumer can protect his supply of riboflavin in milk. The need for removing milk from the doorstep *promptly* cannot be over-emphasized.

A receptacle which is *dark* and *cool* is the alternative if the riboflavin is to be retained. When the milk is taken into the kitchen it should be refrigerated immediately and continuously in the interest of protecting it from light and from warm temperature. Cooking in covered, opaque containers is a further precaution.

The question of the effect of ultraviolet light on the riboflavin content of milk is often raised in connection with irradiation of milk to increase vitamin D content. Losses, if they occur, appear to be negligible.^{15, 16}

Pasteurization—Reports, for the most part agree that there is no significant loss of riboflavin in milk as a result of

pasteurization by the high-temperature-short-time method or by the holding method.^{3, 17-19}

Evaporation—No loss of riboflavin was found when milk was condensed in a batch evaporator for 3 hours at 115 to 120° F. Similarly, there was no loss when milk was evaporated at 120° F. for 35 minutes and then sterilized in cans at 235° F. for 15 minutes.²⁰

Drying—An extensive study of recent date on spray dried whole milk shows its riboflavin content to be equivalent to that of market milk. Samples were obtained from various areas of the world, as well as approximately one hundred samples from various parts of the United States. In addition, a much larger number of samples was obtained from a few plants. The samples of milk were studied while fresh and after various periods of storage.²¹

Storage—No loss of riboflavin is indicated in fresh milk stored for 24 hours at 40° F. in a dark refrigerator.³ Likewise, there appears to be general agreement that no loss of riboflavin occurs in dry and condensed milks under normal storage conditions. Dried whole milk stored for 6 months at 100° F. (in air and also inert gas) showed no loss of riboflavin.²¹ Condensed milk stored for different periods up to a year at 15° C. showed no riboflavin destruction. However, there were losses up to 35 per cent after 6 months' storage at 37° C.²⁰

RIBOFLAVIN IN CHEESE

Processing—The content of water soluble vitamins in cheese will vary with: (1) the amount of whey retained in the curd, (2) the extent to which heat is used, (3) the methods of salting—*i.e.*, whether or not a brine bath is used, which tends to dissolve out the water soluble vitamins, and (4) the amount of exposure of ingredients to air and light, especially during heating.

The temperatures to which most cheeses are subjected are not high

enough to cause much destruction of vitamins. However, the exposure of heated ingredients in large vats and the stirring, cutting, and handling to which cheese is subjected may cause vitamin losses.

The limited data available indicate that about one-fourth to one-third of the riboflavin originally found in the milk from which cheese is made is retained in the cheese. In one study 23 per cent of the riboflavin of the milk was retained in day-old Cheddar cheese made from raw milk.²² The percentage retention of riboflavin in day-old brick cheese was reported by the same authors to be 27.4 per cent; in blue cheese 30.1 per cent.

Pasteurization of milk, either by the holder process or by the high-temperature-short-time method had no deleterious effect on the riboflavin content of fresh Cheddar cheese, nor on the cheese during a 6 months' ripening period. Likewise, homogenization of milk, prior to making blue cheese, had no detrimental effect on the riboflavin content of that type of cheese.²²

Storage—Sacrifice of certain of the vitamins in cheese making is possibly offset to some extent by the fact that they may be synthesized in the outer layers of some kinds of cheese during the ripening process. In one study microorganisms isolated from the surface of four kinds of cheese, synthesized considerable quantities of B-vitamins when introduced into synthetic media. Riboflavin and other B-vitamins, as determined microbiologically, appeared to increase in the surface layers of these cheeses through progressive stages of ripening.²⁵

Other workers found the riboflavin content of Cheddar cheese relatively stable during the ripening process. There was a slight decline in riboflavin during the first 2 months of ripening but an equal rise during the final months to the values found in the fresh cheese.²²

Still other investigators, after analyzing different types of cheese for riboflavin and other B-vitamins, concluded that, whereas certain other B-vitamins appear to vary with the age of the cheese and the ripening process employed, the riboflavin content of cheese is relatively stable to such variations.

RIBOFLAVIN IN ICE CREAM

Storage—One report is available on the stability of riboflavin in ice cream manufactured under commercial ice cream plant conditions from fresh, whole milk, cream (40 per cent fat), cane sugar, and gelatin. Three flavors—coffee, maple, and vanilla—were used. The "over run" was 85 per cent. Samples of each of the three flavors were assayed before and after 7 months' storage at 10° F. The loss of riboflavin was 5.4 per cent.²⁶

THIAMIN IN MILK

Ration of the Cow—The limited number of recent studies on this subject indicate little if any change in thiamin content of milk with fluctuation in the ration of the cow. One study reports that when cows were changed from good winter rations to early spring pasture of rapidly growing grass, there was no change in the thiamin content of the milk.² Investigations indicate synthesis of thiamin in the rumen.^{5, 6}

Light—No evidence was found in the literature that thiamin of milk is affected by sunlight as is the riboflavin in milk. The thiamin content of experimental and market milks irradiated to produce 400 U.S.P. units of vitamin D per quart was not reduced.¹⁵

Pasteurization—A few studies published between 1940 and 1943 agree to a thiamin loss of about 10 to 25 per cent (with the first figure most common). in milk pasteurized by the holding process compared with that found in the original raw milk.^{17, 27, 28, 29} A 1945 study in which milk was assayed im-

mediately before and immediately after pasteurization by the high-temperature-short-time process reports the small loss of 3 per cent.¹⁹

Boiling—A study on the effect of boiling pasteurized milk in preparing babies' formulae shows a loss of 8 per cent in thiamin.³⁰

Evaporation—Milk evaporated in a batch evaporator at 120° F. for 35 minutes and then sterilized for 15 minutes in 4 and 6 ounce cans showed a loss of 27 per cent of its thiamin.²⁰ Earlier findings are in general agreement with these figures and indicate a loss of approximately one-third of the thiamin content as a result of evaporation procedures.²⁸⁻³⁰ Milk condensed at 115 to 120° F. for 3 hours suffered a loss of 3.5 per cent of thiamin.²⁰

Drying—The most recent study available on this subject reports the thiamin content of spray dried whole milk. The authors conclude that "whole milk powder ranks with market milk" in thiamin content.²¹ Earlier studies reported from England on spray and roller dried skim milk indicate a loss of thiamin up to 10 per cent in the spray dried product and up to one-third in the roller dried product.^{28, 29}

Storage—It is reported that "under good operating conditions" no appreciable loss of thiamin occurs in the storage of spray dried whole milk, packed either in air or inert gas, even when held at 100° F. for 6 months.²¹ Condensed milk is reported to lose up to 29 per cent of its thiamin activity when stored for one year at 15° C., and up to 84 per cent when it is stored 4 months at 37° C.²⁰ In a study of several kinds of evaporated milk the amount of thiamin destruction varied with the different milks—two samples reached 50 per cent destruction after one year's storage. Loss was presumably more rapid during the first few months and eventually reached equilibrium.³⁰

THIAMIN IN CHEESE

Processing—Statements made in the section on riboflavin in cheese (regarding the transfer of riboflavin from the curd to the whey in making cheese), largely hold true for thiamin. The relatively low thiamin content of cheese is predominantly due to its high solubility. In a recent study on Cheddar cheese, no actual destruction of thiamin was found to take place in the process of manufacturing the cheese. However, the retention, in the cheese, of the thiamin present in the original milk was only 8.8 per cent.²³ A study conducted in England and reported in 1945 revealed that approximately 15 per cent of the thiamin present in the milk was retained in Cheddar, Cheshire, and Stilton cheeses.²⁴

Storage—Apparently, the nutrient content of cheese with respect to certain vitamins can be augmented during storage by the synthetic action of microorganisms.²⁵ However, in the study of Cheddar cheese cited above,²³ there was a progressive decrease in the thiamin content of the cheese with increasing ripening period. The losses in 12 months ranged from 43 to 73 per cent. Ripening at 58° F. caused greater decreases than ripening at 40° F.²³ In contrast, the 1945 English study revealed that no significant losses of thiamin occurred during ripening for periods up to 42 weeks.²⁴

VITAMIN A IN BUTTER AND MILK

The differences in the vitamin A potency of summer and winter butter and milk are due largely to variations in the carotene content of summer and winter feeds. This fact is clearly evident from a nation-wide coöperative study conducted by the U. S. Department of Agriculture, the Association of Land-Grant Colleges and Universities, twenty-one state agricultural experiment stations, and one federal laboratory. Over 4,000 samples of butter were

analyzed. These extensive studies of differences in vitamin A potencies, as well as possible factors relating to the retention of such values, have been fully summarized so recently^{31, 32} that no effort is made here to refer to individual reports. High points of these studies as they pertain to the subject of this report are indicated briefly.

Ration of the Cow—Of the creamery butter analyzed, 35.7 per cent was considered "winter" butter with an average vitamin A potency of about 11,000 I.U. per lb.; 64.3 per cent was butter produced in summer months when the cows were on pasture, and it had an average potency of about 18,000 I.U. per lb. No significant difference was found, in areas where tested, between the average vitamin A potency of butter on retail markets and the average of the creamery butter produced in this country.^{31, 32}

The average vitamin A potency of the fat in winter butter produced in the United States was about 30 I.U. per gm. and that of summer butter was 49 I.U. per gm. On this basis, the average vitamin A potency of milk containing 4 per cent of fat may be calculated to be 1,140 I.U. per qt. for winter milk and 1,800 for summer milk.³¹ "There is ample experimental evidence that vitamin A potency of milk, and also of butter made from milk, can be readily changed by increasing or decreasing the quantity of carotene in the cow's ration—any condition which tends to increase the lushness of pasture or carotene content of winter fed forages—either silages or hays—will increase the vitamin A potency of milk and butter very much."³¹

Storage—Seven state experiment stations studied the effect of storage on the vitamin A potency of butter. Samples of butter were handled and stored under various practical conditions. The results indicate that both carotene and vitamin A are very stable in butter under the conditions tested; that little if

any loss of vitamin A potency occurs during the periods that commercial butter is ordinarily stored; and that, in so far as the effect of storage is concerned, one would not expect the average vitamin A potency of the butter sold on the retail markets in this country to be significantly different from the average of the creamery butter produced in the country as a whole.³² "This must mean that the antioxidants which occur naturally in butter are exceedingly effective in preserving its vitamin A potency."³²

Other Conditions—Vitamin A appears relatively stable when subjected to the usual processes in the handling of milk. There is no loss of vitamin A potency due either to exposure to sunlight or to ultra-violet light in producing vitamin D milk of 400 U.S.P. units potency.¹⁵ No evidence was found in the literature of losses in vitamin A due either to the short-time-high-temperature pasteurization process or to the holding method. Likewise, there is no evidence of loss of vitamin A as a result of evaporating milk. One extensive study on spray dried whole milk indicated that if any loss occurred during manufacture it was less than 10 per cent.²¹ The vitamin A content was maintained satisfactorily during storage. After 6 months' storage at room temperature, no detectable loss of vitamin A was found in inert-gas-packed powder and only about 6 per cent in air-packed powder. Powder held at 100° F. for 6 months was found to lose 10 to 15 per cent of its vitamin A value in inert-gas-packed powder and perhaps 30 per cent of its value in the powder packed in air.²¹

VITAMIN A IN CHEESE

Processing—Since most of the fat of the original milk is retained in cheese making, much of the fat soluble vitamin A should also be present in the finished product. One study reports the distribution of vitamin A potency

in Cheddar cheese making as follows: 85 per cent retained in the cheese, 7 per cent in the whey, 8 per cent unaccounted for. These figures apply to both carotene and vitamin A. The authors suggest that losses probably occurred in the adherence of milk fat to containers and equipment during processing.³³

Storage—No losses were noted in vitamin A potency when Cheddar cheese was stored for nearly one year. The carotene content showed a slight increase while the vitamin A content was quite constant.³³

In certain mold ripened cheeses, it appears possible that some synthesis of vitamin A takes place since food tables show vitamin A values higher than can be accounted for by the vitamin A found in the milk from which the cheeses originated. One experimental study on blue cheese indicates no change in its vitamin A value during aging.³⁴

CAROTENE AND ICE CREAM

Storage—According to one study (quoted above under the discussion of riboflavin), ice cream showed a loss of carotene during storage which amounted to 15.7 per cent.²⁶

SUMMARY

From the foregoing discussion it is evident that it is impossible to generalize on the all-round stability of the nutrients contained in dairy products as they are subjected to the varied conditions which prevail in the handling of the products from production to consumption. However, it is possible to indicate in broad terms the relative stability of specific nutrients. It may be stated, for example, that riboflavin is remarkably stable except when acted on by light; this photo-chemical reaction is accelerated by heat. Thiamin is somewhat less stable to heat than riboflavin but is not influenced by the light-heat combination. Neither the riboflavin nor the

thiamin content of milk is strongly affected by the feed of the cow. The vitamin A value of dairy products, on the other hand, depends to a great extent on the carotene content of the cow's ration; in general, however, it remains stable during ordinary processing and handling of the products.

Walter Reed Bust in the Hall of Fame

The American Society of Tropical Medicine is sponsoring a campaign for funds in order to have a bust of the late Dr. Walter Reed placed in the Hall of Fame. This niche has heretofore remained empty for lack of funds, although Dr. Reed was elected to the Hall of Fame in 1945. It is hoped to have the funds collected and the sculpture completed so that the dedication ceremonies may be part of the Inter-

national Congress for Tropical Medicine and Malaria to be held in Washington in the spring. The evening of May 12, 1948 has been set aside for the ceremony.

It is estimated that about \$6,000 will be needed. Contributions should be sent to Norman H. Topping, M.D., Secretary-Treasurer of the American Society of Tropical Medicine, National Institute of Health, Bethesda 14, Md.

Recommended Procedure for the Bacteriological Examination of Shellfish and Shellfish Waters*

Laboratory Section

INTRODUCTION

This report replaces the recommended methods of procedure for the bacteriological examination of shellfish and shellfish waters (A.P.H.A., 1943) and has been revised in accordance with the experience of the committee and others who have studied the procedure during the past three years. The committee consisted of: C. A. Perry (resigned); C. T. Butterfield, Leslie A. Sandholzer, Herman Sommer, F. W. Tanner, Cornelius B. Kelly, Charles E. Renn, and J. Gibbard, *Chairman*.

In general, the technique outlined for the bacteriological examination of shellfish is based on recognized procedures which have been developed for the examination of water and sewage. It should, however, be pointed out that there is some evidence not fully confirmed that some coliforms found in salt water may be of little sanitary significance. Furthermore, it is realized that the biology of some shellfish particularly in reference to their normal bacterial flora is not clearly understood. Despite this lack of data, there is every justification for the use of recognized bacteriological procedures for the determination of the coliform group of bacteria, for in the great majority of cases the sanitary engineer can demonstrate beyond doubt

that the presence of coliform organisms is directly related to pollution of human or animal origin.

In this revised procedure, the short methods previously suggested for estimating *Escherichia coli* have been eliminated as unsatisfactory. The chlorine rinse has also been dropped for the same reason. Methods for the examination of frozen shellfish and shellfish products have been included. Mechanical disintegrators have been recommended for preparing shellfish samples and the older procedure of cutting and shaking the shellfish has been discarded.

Shellfish Defined

The term shellfish as herein used refers to any fresh or frozen edible bivalve mollusc, either shucked or in the shell and any fresh or frozen or incompletely sterilized products thereof.

Coliform Group

For the purpose of examination of shellfish and shellfish waters, the coliform group shall be considered as including all organisms which, upon transfer from a positive presumptive test (gas-positive in lactose broth), show fermentation with gas formation in lactose medium containing 0.00133 per

* Revision of Recommended Methods of Procedure. Report of the Standard Methods Committee. STANDARD METHODS COMMITTEE FOR THE EXAMINATION OF SHELLFISH Organized 1938. Published reports: Year Book 1941-1942, A.J.P.H., May, 1943, Official Report of the A.P.H.A., pamphlet, 1944.

cent of brilliant green and 2.0 per cent of bile (brilliant green lactose bile broth).

In most cases, the determination of the coliform group will provide sufficient evidence as to the safety of the shellfish under consideration. However, laboratories charged with the responsibility of examining samples of shellfish other than those known to have been freshly taken from growing areas would be well advised to complete all tests for *Escherichia coli* according to the procedure recommended in the A.P.H.A. *Standard Methods for the Examination of Water and Sewage*, 9th Ed., under "Selective Agar Media for Differentiation," p. 227 and "Differentiation of Coliform Organisms," pp. 228-231. Such examinations may become the basis of legal action and complete tests are recommended.

I—BACTERIOLOGICAL EXAMINATION OF SHELLFISH WATERS

A—Collection and Transportation of Samples

Samples of water from shellfish areas shall be collected at various stages of the tide and shall also be collected at different depths if there is any indication of variations in salinity or pollution due to stratification. The samples shall be collected in sterile bottles and shall be fully protected against contamination both during sampling and after collection. They should be kept at a temperature at or below 10° C. (50° F.) and shall be examined as soon as possible after collection. The samples should preferably be tested within 12 hours from the time of collection and in no case shall samples which have been held for more than 30 hours be tested.

B—Field Record

A record of environmental conditions made at the time of collection of the

sample should accompany all water samples collected during the course of a survey to establish the sanitary condition of shellfish waters. This record shall include the following essential information:

- Date and hour of collection
- Exact location of the sampling station

Where possible the following supplementary data shall be obtained in order to interpret the bacteriological findings.

1. State of the tide
2. Direction and velocity of currents
3. Direction and velocity of the wind
4. Temperature and density of the water
5. Depth of the water and depth at which the sample was collected
6. Temperature of the air
7. Notes on any unusual conditions which may affect the sanitary quality of the water
8. Record of rainfall in the immediate past

A suitable form to be used for reporting this information may be found in Sec. IV A.

C—Procedure

Examination for bacteria of the coliform group shall be made by primary inoculation into plain lactose broth (see Sec. III D) with incubation at 35°–37° C. After incubation for not more than 48 hours definite gas formation shall be recognized by the presence of visible gas in the upper end of the inverted fermentation tube or by the presence of effervescent gas bubbles visible only when the tube is shaken.

Detailed instructions on the collection of samples and inoculation of media may be obtained from the A.P.H.A. *Standard Methods for the Examination of Water and Sewage*, 9th Ed., p. 190, et seq.

1. Inoculation

Inoculate—

- a. Not less than 3 tubes with 10 ml. of undiluted water
- b. Not less than 3 tubes with 1 ml. of undiluted water

- c. Not less than 3 tubes with 1 ml. of a 1 in 10 dilution of water (in 1 per cent salt solution)

(These dilutions may be altered to suit the degree of contamination of the water, but in no case should less than three dilutions be inoculated.)

2. Presumptive Test for Coliform Organisms

Incubate tubes for 18–24 hours at 35°–37° C. Record gas formation in each tube.

a. *Gas present*—Any amount of definite gas constitutes presumptive evidence of the presence of coliform bacteria and must be confirmed as described in step 3 below.

b. *No gas*—Incubate negative tubes an additional 24 hours making a total of 48 hours incubation. Record gas formation.

(1) Gas present in any amount constitutes a doubtful test which must always be confirmed (step 3).

(2) Absence of any gas after 48 hours of incubation constitutes a final negative test.

3. Confirmation

All positive gas tubes must be confirmed for bacteria of the coliform group.

Transfer a loopful (3 mm. diameter loop) of culture from the gas-positive primary lactose broth fermentation tube to one of brilliant green lactose bile broth (see III E).

a. Any amount of definite gas formation within 48 hours at 35°–37° C. constitutes a positive test for bacteria of the coliform group.

b. Absence of gas after 48 hours' incubation constitutes a negative test for bacteria of the coliform group.

4. Differentiation of coliform organisms

Conduct all tests for relative density of species of the genera *Escherichia* and *Aerobacter* according to the procedures recommended in the A.P.H.A. *Standard Methods for the Examination of Water and Sewage*, 9th Ed., under "Selective Agar Media for Differentiation," p. 227

and "Differentiation of Coliform Organisms," pp. 228–231.

D—Expression of Results

The numbers of bacteria of the coliform group shall be expressed as the most probable numbers (M.P.N.) per 100 ml. of sample. The M.P.N. shall be determined from the table of most probable numbers given in Sec. V.

II—BACTERIOLOGICAL EXAMINATION OF SHELLFISH

A—Collection and Transportation of Samples

Individual containers of shellfish samples shall be marked for identification and the same mark shall be placed in its proper place on the descriptive form which accompanies the sample.

Shellfish samples shall be kept at or below 10° C. (50° F.) until examined, but under no condition shall they be permitted to come in direct contact with ice. A sample shall be considered unsatisfactory which has been improperly handled after collection. Samples of shellfish should preferably be tested within 12 hours from the time of collection and in no case should they be examined if they have been held for more than 30 hours.

Shell Stock

In general, ten or more shellfish, judged to be representative of the lot under examination shall be selected and prepared for transportation to the laboratory. Oysters and hard-shell clams (quahaugs) should have deep bowls, unbroken lips, and shells tightly closed. The quantity of shellfish submitted shall be sufficient to produce not less than 200 ml. of shell liquor and ground meats. The shellfish shall be placed in a suitable sterilized container such as a can with watertight lid or a canvas or waterproof bag. All shellfish for bacteriological examination shall be handled aseptically.

a. Gas present—Any amount of definite gas constitutes presumptive evidence of the presence of coliform bacteria and must be confirmed as described in step 3 below.

b. No gas—Incubate negative tubes an additional 24 hours making a total of 48 hours incubation. Record gas formation.

(1) Gas present in any amount constitutes a doubtful test which must always be confirmed (step 3).

(2) Absence of any gas after 48 hours of incubation constitutes a final negative test.

3. Confirmation

All gas-positive tubes must be confirmed for bacteria of the coliform group, as described under Section 3 in the procedure for the examination of shellfish waters, by transfer to brilliant green lactose bile broth.

4. Differentiation of Coliform Organisms

Tests for relative density of species of the genera *Escherichia* or *Aerobacter* shall be made by the method described in Section 4 in the procedure for the examination of shellfish waters. Any laboratory charged with the responsibility of examining shellfish and desirous of determining the relative density of the various members of the coliform group should adhere strictly to the prescribed procedure. Such examinations may become the basis of legal actions and short cuts are not recommended.

E—Colony Counts

A standard colony count of shellfish samples has been found to be of value as an index of general sanitation and refrigeration.

Colony counts shall be made by inoculating various amounts of sample, as prepared under Section II—A, above, into the tryptone glucose extract agar (see Sec. III F) and incubating plates at 35°–37° C. for 48 hours.

The method of preparing plates and

making the counts shall be that recommended by the A.P.H.A. *Standard Methods for the Examination of Dairy Products*, except that milk shall not be added to the medium (*Standard Methods for the Examination of Dairy Products*, 8th Ed., 1941).

F—Expression of Results

The numbers of bacteria of the coliform group shall be expressed as the most probable numbers (M.P.N.) per 100 ml. of sample. The M.P.N. shall be determined from the tables of most probable numbers (Sec. V).

III—MEDIA—COMPOSITION AND PREPARATION

A—Materials

The materials used for the preparation of media shall be as described in *Standard Methods for the Examination of Water and Sewage*, 9th Ed., p. 184.

B—Adjustment of pH

The method of adjustment of reaction shall be as given in *Standard Methods for the Examination of Water and Sewage*, 9th Ed., p. 185.

C—Sterilization

The method of sterilization of media shall be as given in *Standard Methods for the Examination of Water and Sewage*, 9th Ed., p. 185.

D—Lactose Broth:

Beef Extract	3.0 gm.
Peptone	5.0 gm.
Lactose	5.0 gm.
Water (Distilled)	1 000.0 ml.

Adjust the reaction so that the pH after sterilization will be between 6.7 and 7.1. Place in fermentation tubes and sterilize in the autoclave at 15 lb. for 15 min. (121° C.). Cool rapidly after removal from the autoclave.

A 10 or 20 per cent solution of lactose in distilled water may be prepared and sterilized in the autoclave (15

lb. for 15 min., 121° C.), or by heating in an Arnold sterilizer at 100° C. for 1½ hours. Add this solution to sterile broth (without lactose) in amount sufficient to make an 0.5 per cent lactose solution, tube with proper precautions for preserving its sterility, and sterilize at 100° C. for 30 minutes.

It is permissible to add by means of a sterile pipette directly to a tube of sterile nutrient broth enough of the lactose solution to make the required 0.5 per cent concentration. The tubes so made shall be incubated at 35°–37° C. for 24 hours, as a test for sterility before they are used.

E—Brilliant Green Lactose Bile Broth
(2 per cent)

Dissolve 10 gm. of peptone and 10 gm. of lactose in not more than 500 ml. of distilled water. Add 200 ml. of fresh ox bile or 20 gm. of dehydrated ox bile dissolved in 200 ml. of distilled water. No dehydrated ox bile shall be used which has a pH of less than 7.0. Make up with distilled water to a total of at least 975 ml. and adjust the reaction to pH 7.4. Add 13.3 ml. of a 0.1 per cent solution brilliant green (certified for culture media) in water;

make up to a total of 1,000 ml. and filter through cotton.

Distribute the medium in tubes provided with inverted vials. Sterilize in the autoclave at 15 lb. for 15 min. (121° C.).

The reaction after sterilization shall be not less than pH 7.1 and not more than pH 7.4.

F—Tryptone Glucose Extract Agar

	Per cent
Agar, best quality, not oven dried	1.5
Beef Extract	0.3
Tryptone	0.5
Glucose	0.1
Reaction—pH 6.6 to 7.0	

(The above media may be purchased in dehydrated form from firms of known reliability. The preparation of these media should conform to directions given above. Dehydrated media are recommended in the case of Eosin Methylene Blue Agar and Brilliant Green Lactose Bile Broth.

Large laboratories obliged to make their own media would be well advised to run comparative tests from time to time, using one of these well known commercial dehydrated products for the comparison.)

VI—DEFINITIONS

1. Shellfish

The term shellfish as herein used refers to any fresh or frozen edible bivalve mollusc, either shucked or in the shell and any fresh or frozen or incompletely sterilized products thereof.

2. Coliform Group

For the purpose of examination of

shellfish and shellfish waters, the coliform group shall be considered as including all organisms which, upon transfer from a positive presumptive test (gas-positive in lactose broth), show fermentation with gas formation in lactose medium containing 0.00133 per cent of brilliant green and 2.0 per cent of bile (brilliant green lactose bile broth).

APPENDIX I

The Letsch oyster opener has been found useful for those who are inexperienced in opening oysters. It is essentially a heavy oyster knife powered

by a rack and pinion which forces the knife through the hinge of the oyster, severing the adductor muscle from its attachment to the top shell. The oyster may then be held by the bottom shell over the pint jar, the shell liquor drained and the bottom adductor muscle cut. The parts of the machine which come in contact with the oyster may be sterilized by flaming or immersing in 70 per cent ethyl alcohol or boiling water.

APPENDIX II

Disintegrators — The disintegrators mentioned in Section II C 1 c, page 1125, consist of the base housing a high speed motor (10,000–16,000 r.p.m.) which drives knives fitted in a cup which is placed on the top of the motor unit. These disintegrators are in production by a number of manufacturers and may be obtained from almost any laboratory supply house.

A metal cup, preferably of stainless steel or aluminum, has advantages over the glass cups usually furnished with the machine, particularly with regard to sterilization either in the autoclave or by boiling. These also may be obtained from the laboratory supply houses.

Experience with the particular make of disintegrator will dictate final establishment of grinding time. Care should be taken to avoid too long a grinding because of the danger of occlusion of excessive amounts of air in the mixture.

* Deceased

Is Aviation Medicine Industrial Hygiene?*

BRIG. GEN. EUGEN G. REINARTZ, M.D., F.A.C.P., F.A.M.

U. S. Army (Ret.), San Mateo, Calif.

FOR the past century efforts have been made to bring the problems of industry, the knowledge of medicine and related sciences together for the solution of these, in the interests of both the industry, as a whole, and those individuals participating in industry.

During the period 1840-1880 attempts were made to better the lot of the working man; however, after that time stress was laid on disease prevention, *per se*, and the working man, as an individual, relegated to a secondary role. During World War I the pendulum swung from particularized disease prevention to industry as a whole. It was during this time that a system of medicine was inaugurated in the Aviation Section of the Army Signal Corps that is now called "Aviation Medicine." It was a radical departure from any previous effort of similar nature. This system was developed in 1918 for the then newly-born Air Service of the Army and has gradually developed to encompass the entire field of aviation, civil, civilian governmental agencies, and the armed services.

A small band of inspired doctors under the competent leadership of Brigadier General Theodore Lyster formulated plans for the care and treatment of aviators. They were wiser than their generation, for in my opinion no similar

effort of like nature had been developed in any field of endeavor. It was the beginning, on a national scale, for the first time, of a system of medicine that would encompass the entire activities of personnel engaged in one of the arts—the art of flying.

This group of men were believed visionary and had to weather the rebuffs and hostility of those for whom they were laboring so conscientiously and intensely. They were determined in their convictions and were able to organize a research laboratory and a school for the indoctrination of others who had the temerity to follow where they had dared to pioneer.

Through the years between World War I and World War II this school—the School of Aviation Medicine, now located at Randolph Field—continued through its graduates to spread the leaven of the necessity for medical supervision over those who would learn to fly and those who had finished their training and had received their coveted aeronautical ratings. This indoctrination of Air Forces personnel early was an uphill battle and brought with it many disheartening experiences. To those of us who pioneered in this work it seemed at times that the "game was not worth the candle" and that we were "voices crying in the wilderness" of prejudice and antagonism—as is always the situation when one dares to institute an innovation, even though it is in what, at the time, and at a later date is proved to be, the best interests of the ones who

* Presented before the Industrial Hygiene Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946.

were its most vociferous opponents. In this uphill struggle for the recognition of Aviation Medicine, resistance came from an unexpected quarter in that we were oftentimes opposed by our own medical brethren of the Medical Department assigned to other duties than with the Air Forces. Nevertheless, Aviation Medicine being solidly founded developed and in the Services came to full fruition during World War II.

With the formation of the Division of Aeronautics in the Department of Commerce, the first director wisely ruled that the division should have a medical department. The doctors assigned to these duties were graduate flight surgeons and indoctrinated in this work in the Army. They formulated rules and regulations patterned after those of the Army but modified to meet the needs of a civilian population learning to fly but who could not be supervised as were Army personnel.

As civil airlines began to develop, the management of these lines soon realized that medical supervision of their flying personnel was a "must" if their operations were to be successful, from the standpoint of the health of the pilots as well as that of the public that had every right to demand the ultimate for the pilots' medical care. This has paid dividends, as I know of no airline—passenger or freight—that does not have its own thoroughly organized medical department with flight surgeons to look after the especial needs of their flying personnel.

Airplane manufacturers, too, have realized the necessity for and the effectiveness of aviation medicine in connection with those engaged in flying. These large plants have their regular medical establishments to care for the needs of their employees. However, they also have doctors who have had specialized training in those problems that beset flyers—especially those engaged in test flying new types of airplanes.

Aviation Medicine is medicine, in all its phases, applied to the art or profession of flying. In its application it transcends occupational medicine and industrial hygiene, as practised. Aviation Medicine has a higher significance than these, in that it encompasses both and goes farther, considering as it does the total personality of the flyer in any and all of the environments in which he finds himself, in the air, on the ground, at work, at play, and in his relaxations. It is a full-time job and those engaged in Aviation Medicine must be especially chosen, as not everyone who would practise this type of medicine is qualified for it.

At the Schools of Aviation Medicine of both the Army and the Navy—the only organized schools in the world giving formalized training in this specialty—emphasis is laid on the selection of doctors who would become flight surgeons. This selection is made academically, militarily, physically, and psychologically. I have for years defined the flight surgeon as an outstanding doctor, a graduate of the School of Aviation Medicine who has the attributes of the family physician, lawyer, and priest, with a strong bent for psychopathological medicine. During the past war it has been necessary for me to add the term "technologist" to my definition, because of the tremendous technological advances made in aviation, and concerning which the flight surgeon must know much.

The Schools of Aviation Medicine mentioned are supplemented by their own well organized research laboratories as well as by the Aero Medical Laboratories at Wright Field, Ohio, and Bethesda, Md. In the field of civilian aviation each large airline and airplane manufacturer has its own aviation medical research laboratory. These all have for their goal the solution of many problems from the human standpoint with which the profession is faced, as

aviation approaches the era of supersonic speeds, illimitable altitudes and interplanetary communication that staggers the imagination.

It might be well to detail how the flight surgeon works in this system of medicine and how it is applied in the Military Services. Prior to World War II all medical officers assigned to Air Forces duty were flight surgeons. However, with the tremendous expansion of aviation during the past six years such assignment was not possible. Nevertheless, over 5,000 doctors, thoroughly indoctrinated in Aviation Medicine, were added to the Armed Forces during this period. It is the hope, in the Army Air Forces certainly, that with the cessation of hostilities, all doctors assigned to duty with flying personnel will again be thoroughly versed in the problems of aviation by having attended the service schools and having received the required designation of flight surgeon.

In the Services the application of Aviation Medicine brings it into contact with the cadet applicant immediately upon his presenting himself for the purpose of pursuing flying training. From that time on, throughout his flying life, he is never outside its beneficent scope. During his training period he is continually under observation as to his physical well-being and, more especially, as to how he is adapting himself psychologically to the flood of new sensations and situations that he is experiencing in an effort to help him over these early hurdles of his flying life.

After the cadet has earned his wings and passes on to his transitional training period, a period fraught with many dangers, since at this stage he may think himself invincible in a plane, he may do something foolish that may lead to disaster. Having weathered this period the young man is then detailed to an operational unit. Here he becomes a part of an air crew and, depending on his assignment, he may be sent into any

part of the world. The flight surgeon is always at his side ready with advice, counsel, and indoctrination to make the air crewman's life more livable in several senses of that term.

If assigned in the Arctic his flight surgeon will give him instructions, to refresh his memory, relevant to the medical aspects of flying generally but specifically how to use protective clothing, warning him at the same time against such hazards as excessive perspiration in sub-zero weather. He is taught how to survive should he be forced down on snow or ice; how to use his emergency communications set, and how to use his parachute silk for protection and the building of temporary shelter. Instructions in the use of such other emergency equipment—fire making, fishing, snaring, hunting, etc.—are given and all emergency equipment furnished. The deleterious effects of glare from the snow, ice, and sea are brought to his attention, and goggles of an appropriate color are supplied. One of the flight surgeon's most difficult indoctrinations of flying personnel in these regions is the combating of lonesomeness, especially during the long winter night when monotony and boredom grip the entire command.

If the airman is assigned to duty in the tropics protection against the sun is stressed, again with reference to clothing and general bodily protection. The necessity of protection against tropical diseases, insect bites, and the use of prophylactic drugs is continually dinned into his ears. The taking of these drugs is a medically supervised procedure and statistics of the last war have proved how effective this was.

Instructions were and are now given airmen on how to survive in the jungle. Here too emergency equipment is furnished those who might suffer such a devastating experience, this included, in addition to the usual survival equipment, mosquito bars, and a particular-

ized emergency ration. Instructions are also given in the recognition and protection against venomous reptiles, the effect of enervating heat, and conservation of strength, the necessity of using salt and, as always, the psychological effect of such an experience.

Ditching procedures for various types of aircraft, as each has peculiar characteristics in this emergency, were first worked out by our British allies. When it became necessary for our Air Forces to know something about such techniques the same were worked out under the supervision of The Air Surgeon of our forces. When our airmen "ditched" it became necessary to rescue them, and this brought with it "air-sea rescue." Such air-sea rescue was drilled into flying personnel, not only those who might have to be rescued but to rescuing crews as well. The daring rescues, at times from under the very eyes of the enemy, make one of the most thrilling and hair raising records of the late war.

Instructions in first aid to the injured is of paramount importance, for where is such knowledge more needed than in a bomber engaged in aerial combat, with a crew of from two to ten, some of whom may be seriously wounded or unconscious from anoxia, many miles and hours from its home base.

During active operations the real flight surgeon saw his men prior to the "take off," giving each one a last critical survey to see that each man was fit for the hazardous mission he was about to begin. Upon the return of the flight this same flight surgeon, after having "sweated out" the intervening period, was ready and waiting on the landing strip to care for those who were in need of his professional ministrations and to give a welcome to those who had returned unharmed.

Many a heart-warming tale is told with pride by returned air veterans of how their "Doc" was always on hand and how they had learned to look for

his cheery, confident face immediately upon landing.

The flight surgeon, who is a flight surgeon in fact, is one of the greatest morale builders in any Air Forces outfit. He is continually consulted by the Commanding Officer and has direct entree to his office. I am informed that this same procedure is in vogue among the larger airlines, where the senior aviation physician has a direct approach to the president of the company. It must be so, for how could the medical officer or the senior physician discuss with any one but the "tops" the oft intimate problems brought to him by the flying personnel of his group!

Aside from those factors that are primarily due to war and the assignment to strange parts of the globe by reason of such war, the flight surgeon has many other things concerning which he must indoctrinate his air crew members. The matters concerning which I shall now speak are those factors that are inherent in flying itself and that have their effect upon all personnel who participate in powered aerial flight. It is in connection with these conditions that the flight surgeon's knowledge of technological matters is called upon, and he must work in close harmony with aeronautical engineers and others of the engineering profession for the solution of the many problems yet unanswered.

Some airplanes, even of the present, have been developed by aeronautical designers and engineers to such an extent that the human economy, not being adaptable to similar developmental changes, has lagged behind. The limitation of the human body with its finite characteristics must be brought to the attention of the designers and engineers so that adaptive measures for their proper human manipulation may be developed. Whose responsibility should this be but that of the medical man versed in the physiological and psychological problems of aviation?

The effect of decreased atmospheric pressure as one rises to altitude affects all living organisms. Altitudes may be reached in which this factor alone may cause death. The engineer in designing an airplane is interested abstractly in developing a machine that will attain a certain altitude. The flight surgeon, however, visualizes the individual who will be called upon to handle the controls and be a functioning organism when the engineer's maximum altitude is reached. His advice to the engineer is pressurization which on consultation is determined upon. The next question that then arises is "How much of a shock can the human economy tolerate in the case of explosive decompression?" Here again the answer is forthcoming from the flight surgeon by reason of the physiologic experimentation done in the laboratory. This question has assumed great practical importance in commercial aviation as airlines are now projecting transcontinental flights at an altitude of 40,000 ft., where the atmospheric pressure is reduced to 2.72 lbs. per sq. in. Flight surgeons have been asked to express an opinion as to how much pressurization should be used. The optimum, of course, would be sea level pressures of 14.6 lbs. per sq. in., but these the engineers believe too sanguine, from the standpoint of engineering. Some compromise is being arrived at, so that all passengers may fly at a pressurized altitude that is compatible with good engineering practices, safety, and comfort.

Another and more pronounced altitude effect is the diminution in the partial pressure of oxygen. But few are able to maintain normal functioning, by reason of anoxia, above 18,000 feet, and none can function without supplemental oxygen at the height of Mt. Everest. "Bends" and "Chokes," the symptoms of anoxia, have been known by the flight surgeon for years. It was through his efforts, again in consultation with

engineers, that a suitable oxygen mask was developed. During the past war when at extreme operational altitudes the oxygen mask froze, it was the experimental work done by flight surgeons, working first in the theater, that brought about an improvement in this apparatus with a most gratifying decrease in the number of disabilities due to anoxia as a result of frozen masks.

The type of clothing worn by aviators to protect them from the extreme cold, another of the disabling factors encountered at altitudes, had its modest beginnings in the research made by a flight surgeon working obscurely in the wilds of Alaska. This has now progressed to the point of electrically heated clothing, as well as other types, so that comfort and protection may be had under any of the vagaries of climate encountered.

The illusions of the senses as related to the internal ear that caused so many deaths by crashing in the fatal "spin," were elucidated by a flight surgeon in 1928. His clear exposition and interpretation of the illusions were the basis for the development of instruments that have made instrument flight possible and without which no long distant flight could possibly be made.

The success in the transportation of sick and wounded during the last war is a great tribute to the flight surgeons, who for more than 25 years have urged this mode of transportation of patients as being practicable, feasible, humanitarian, and life saving.

So it is that whether one be speaking of the subjects already discussed or the effects of vibration from the newly developed jet plane, or noise, or speed, or noxious gases, one finds the flight surgeon deeply engrossed in study in his laboratories to assist the engineers in the elucidation of the problems as they affect not only the flyer, but everyone whom they might harm.

It is worthy to note that modern application of an ancient protective device

—the body armor—was the development of a flight surgeon, who, working almost alone and against great odds, was able to have aircrews volunteer to wear his device. It was but a short time following the survival of one, who surely would have been killed, that the "flack suit" was demanded by many. The numbers of those wearing this garment, who have been saved from certain death, is legion.

With the tremendous increase in the speed of airplanes the question of the safety of the pilot, in a pursuit plane particularly, should anything occur to render it unmanageable, immediately presents itself. It is at once apparent that the human body cannot tolerate air pressures developed at speeds such as are possible even today. Some means of getting the pilot out of the plane had to be developed. Ejection, therefore, had to be considered. This is not a new principle. Ejection seats were developed by the German Air Force and are being improved by us, through consultations and experimentation between our engineers and flight surgeons. It will be necessary to eject the pilot, in a capsule, which when slowing down will enable the pilot automatically to rid himself of the capsule and permit the use of his parachute.

Again in the matter of speed what will happen to the human economy when supersonic speeds are reached? The engineer is unable at this time to predicate what will happen to the structure of the airplane and we are at a loss to know, as yet, what will happen to the individual flying this plane. Can it be possible that the airplane, as now constructed, with its human cargo, will, as one engineer expressed it to me "hit a solid wall"? The supersonic "wall" has not yet been broken through and that which lies just before it and just beyond it is an unknown quantity of the utmost magnitude and will tax the acumen of all who work on this baffling problem.

Researches are now being made by aviation medical experts into the effects of cosmic rays on flying personnel because of the heretofore unbelievable altitudes to which airplanes will ascend within the immediately foreseeable future.

One of the greatest differences between Aviation Medicine and that which is known as occupational medicine or industrial hygiene lies in the stressing in Aviation Medicine of the psychological reactions of those who come under its authority. Aviation Medicine considers the individual not only as a single functioning organism in a profession, but as a total integrated personality. The stresses and strains of military and airline flying, to say nothing of the hazards of battle flying, as practised and envisioned in the future, are such as to produce personality difficulties in those less well integrated than are their fellows. The flight surgeon must be ever on the alert to catch those subtle changes and recommend remedial measures. This phase of his work in my opinion is one of the most important, of his duties.

Much has been written here concerning a relatively new system of medicine having its world-wide application to the problems of aviation. The question naturally arises as to how successful is such a system of medicine in accomplishing that which it has set for itself. The answer is immediately at hand, as it has been reported to me by a reliable informant that Messerschmitt, the famous German airplane designer, after his capture, made the statement to my informant that the American aircrewman knew more concerning aviation medical matters and was better indoctrinated in how to care for himself than were even the German physicians assigned to aviation duty.

The situation, in connection with Aviation Medicine, in an organized body as the Air Forces, is ideal for the de-

velopment of a system of medicine such as has been outlined. There are those who will state that such practices as outlined cannot be carried out in civil pursuits, and yet it is working in civilian aviation. Certainly civil aviation does not have the control over its personnel that is exercised by the Services. Granted that the principles enunciated are not as fully applicable in all phases, nevertheless in civil aviation, as in the Air Forces, there is a parallelism in this respect that is splendid and augurs well for the future of the flying profession.

It must be remembered, too, that while the flight surgeon gave original impetus to aviation medicine, the effects of which have spread beyond the boundaries of the Services, many of the advances that have been described have been made through the agencies of civilian laboratories.

It has been my pleasure to enumerate to you some of the specific ways in

which we who practise Aviation Medicine consider our work. There are many facets of this rapidly developing art that, because of the limitations of time, cannot be touched upon. Suffice it to say that there is no phase of a flyer's life or activity in which the flight surgeon does not have a deep and abiding interest and concern.

The answer to the question put to me "Is Aviation Medicine Industrial Hygiene?" may be answered in the affirmative with "Yes, it is industrial hygiene and more" since it goes further, and in my opinion, is broader in its concepts and certainly in its practices than is industrial hygiene.

There is much that industry at large may learn from the flight surgeon. Therefore, the principles and practices of Aviation Medicine, its ulterior motives being understood, may well be used as a pattern in the solution of the medical problems in industry.

Program Audit—A Device for Reflecting Public Health Performance*

EVELYN FLOOK AND JOSEPH W. MOUNTIN, M.D., F.A.P.H.A.

*Methods Examiner, and Medical Director, U. S. Public Health Service,
Washington, D. C.*

ALL persons concerned with public health administration must have become disturbed about the increasing volume and complexity of reports and records that characterize our routine operations. Paper work in public health has long since passed the stage of being a source of irritation; it now constitutes a significant drain on the time of professional and technical personnel and thus has become an appreciable item in health department budgets. Part of the need for records arises out of the numerous occasions the primary worker will have for examining change in a case or situation under observation or for influencing a course of action. In greater measure it would seem that the requirements for both records and reports are determined by persons in supervisory positions and by agencies that administer grants-in-aid either financial assistance or technical services, in lieu of money grants. Clear-cut administrative reasons for these latter requirements in particular are always difficult and often impossible to elicit, much less justify.

It is traditional among our citizens to blame their government for most of their grievances, either real or imaginary, and for one layer of government to pass the blame on to another. Because the authors happen to be situated at the federal end of the line,

we could choose between only two courses—either reverse the process of fault finding, or accept the task of doing our part in trying to correct a situation which, we think, all agree is becoming truly serious. The latter course of action was chosen. Our methods and observations are presented with the conviction that they are timely and of general application in public health practice.

Those of you who occupy administrative positions in state health departments will recall that three years ago the authors began the collection of information on which to revise the requirements of the U. S. Public Health Service for the plan of organization and operation which a state submits annually in justification of federal funds for general public health purposes. On the basis of observations and in consultation with division directors in state health departments, a new type of plan was developed and has since been placed in general use, after clearance with the Committee on Business Management of the State and Territorial Health Officers. Although somewhat of a digression, a very brief description of the plan seems in order at this point, since it sets the stage for the audit procedure which completes the system of controls.

The plan submitted prior to the beginning of a fiscal year sets forth the funds that are available locally for support of the program, together with those that are contemplated from other sources. In so far as practicable, funds are assigned to specific functions. In

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946.

like manner, the staff is described by numbers in professional categories and according to functional assignment, wherever this is possible. There is also a statement of facilities operated by the department and the services associated with them. Each significant function of the department is then depicted by indicating—after a series of descriptive phrases—whether the activity is represented in the program and, if so, whether it is a major or minor item. By using an appropriate symbol, the reporting officer indicates whether there has been increase or decrease in the activity as compared with the previous year, and whether he plans to expand, contract, or maintain about the same level of operation in the ensuing year. After review and acceptance, this plan constitutes an agreement between the U. S. Public Health Service and the state health department concerned. Now the question is: how to determine later whether the grantee—in this case the state health department—has carried out the terms of the trust. In other words, what criteria shall be used in assaying performance or in measuring progress or retrogression?

It did not seem feasible to adapt the traditional quantitative expression of activities to our needs without falling back into the very fault we were trying to correct—the accumulation of voluminous statistical data. Substitution of professional judgment for a mass of uninterpreted figures appeared to be a more reliable means of determining what really makes a program “tick.” We decided, therefore, to explore another technique in which we would apply to program operation the principle of “audit”—meaning, according to Webster “to examine and verify.” The purpose of this exploration was to determine how the audit procedure might be adapted to a simplified set of requirements in public health administration. In this paper please keep in mind

the words: “*A simplified set of requirements in public health administration*” because what we propose is not geared to epidemiology, administrative research, or any other requirement beyond that of enabling a grant-in-aid agency to determine whether the aided program has been pursued effectively in accordance with the approved plan. Neither records of population experiences nor those used for internal administration and self-evaluation of health department services are involved in this discussion.

According to the traditional philosophy underlying grants-in-aid in the field of public health, primary responsibility rests with the grantee—not the grantor—for the development of programs. This, of course, must be done within a framework of reference that is determined by the legislative act or trust under which the funds are made available. Beyond the original understanding, which an approval of plan signifies, the operator of a program should be free to work out his own procedures. Acceptance of a grant carries with it responsibility for achieving reasonable accomplishments and for observing the dictates of good administrative practices, including ordinary fiscal honesty. At the same time, those who represent sources of funds need to obtain general understanding of those programs, to determine whether they are operating according to covenants, and to appraise results in relation to expenditures. With these general principles there is common agreement, but their application has given rise to a very cumbersome system of records and reports for which we now propose a simpler system of program audits.

The audit device is not presented here as a perfected instrument for solving the administrative problem of relating actual performance to plans previously agreed upon. Since there is still much to be done in its development, you may regard this discussion as somewhat premature.

On the contrary, your consideration of the subject has purposely been invited at this stage so that there might be more general understanding of our objectives. Because health officers have a mutual interest in this problem, it is hoped they will contribute to our thinking and efforts in this direction before a fixed procedure has evolved.

The underlying principle of program audit is field observation of actual operations by persons of experience and judgment, and heart to heart—or at least, face to face—discussion between representatives of the supporting agency and of the operating agency. Through such observations and discussions more intimate knowledge concerning a program can be gained in a day or two than through weeks of study of summary activity reports. Program audit has the added advantage of combining consultation with appraisal under circumstances which can be made as informal as the occasion warrants.

For instance, traditional reports on clinic activities usually call for the total number of persons, by prescribed classifications, that have been served over a given period, together with counts of persons disposed of in several significant fashions. True, some idea of the general effectiveness of the program and of its accomplishments could be derived from such data, but much, if not all, of its value is lost in the routine tabulations that are generally made. The authors maintain that a personal visit to a random sample of these clinics would reveal a great deal more. Spot review of the operating case records taken directly from the clinic file would give all information contained on a periodic report especially prepared for submission to a supporting agency and requiring hours of time both in preparation and review. In addition, it would be possible to determine at first hand whether the case load of the clinic justifies its operation; whether it is accessibly located; whether

the clinic hours are convenient for the patients to be served; how well the session is organized; whether it is conducted with due regard for the patients' feelings—causing them a minimum of discomfort and embarrassment; whether waiting, interviewing and treatment rooms are comfortable and well arranged; whether interviewing is skillfully done; whether equipment is sufficient and well cared for; whether there is an adequate staff of properly qualified personnel in attendance; and whether acceptable diagnostic and treatment procedures are used. In other words, by actual observation a competent surveyor can differentiate between good and poor performance in a way that it is not possible to express statistically.

Consequently, the thesis that intelligent consultants in the several fields of public health quickly develop reliable impressions of people, equipment, and character of service, that are more revealing than any quantitative enumeration of activity, is the primary base upon which the scheme of program audit is founded. On the other hand, a *completely* unguided series of observations, made by a number of different persons cannot be trusted entirely to elicit a comparable body of information.

While the expert apparently is able to form an opinion concerning a situation at a glance, an uninitiated person goes through a ponderous process of weighing every element of a program before reaching a conclusion. However, if you pin the expert down, you will find that—unknown to himself, perhaps—he, too, applies certain criteria in arriving at his conclusions. In short, for program audit, professional judgment of a program must be tied to a real system of observations and follow a defined method of approach. We have consulted with numerous specialists in the various health fields for the purpose of learning the particular points on which judgment

should be based, thus minimizing the chance of personal bias being mistaken for sound professional judgment.

Prior to visiting the state to begin work on the audit—proper, preliminary study is made of commitments in the plan, particularly those concerned with funds, staff, equipment, and service items that the respective programs comprise.

From this preliminary synopsis the program auditor—always a technically trained person and usually a specialist in the particular field under study—forms an idea of what he expects to find when he reaches the scene of operation with respect to the general appropriateness of resources and methods of operation and of how these elements fit together. These impressions will be confirmed, modified, or completely refuted by the situation he actually finds during his visits. Explanation regarding questionable situations suggested by this preliminary study, as well as verification of approved situations, will be obtained in the field.

When the program auditor visits the area he first determines whether there are any peculiar problems that materially affect the program under scrutiny, whether such problems are susceptible to solution, and if so, whether reasonable effort is being made to get them solved. With this knowledge to serve as a guide, he proceeds to make observations that will reveal how the program is actually operating, reasons for any weaknesses that he finds, and conditions contributing to outstanding accomplishments. Conclusions concerning the *quality* of services rendered are based on several approaches: Well formulated questions designed to reveal the knowledge, attitudes, and skills of the operating staff with respect to the various elements of the program; field visits with staff members for observation of the techniques in use and reaction of persons served; spot check of operating

records to determine actual accomplishments in the most significant aspects of the program; examination of the educational materials used; and determination of methods employed by the operating agency for evaluation of the effectiveness of the program as a whole or of any particular component element. From his spot check of service records the auditor determines also the coverage of services rendered—in terms of geographic area and population reached and in terms of essential items included. He observes economy of operations; adequacy and arrangement of quarters, equipment, and supplies; general morale of the staff; progress toward accomplishing objectives; staff advancement; and improvement of program. As observations are made from time to time throughout the year the consultant makes notes of his findings for later reference. At the end of each visit he records on a report sheet designed for the purpose pertinent comments regarding each observation. On a predetermined date, reports of the several consultants—containing the brief, concise statements that have been entered cumulatively—are summarized into an overall audit report for the health department as a whole.

Although the types of observations are stated here in very general terms, we have systematized the procedure to be followed by preparing for the use of all program auditors an outline that is used as a guide in performing the audit. Usually casual questioning will lead to the selection of sample records or current situations for careful checking. Where counts are necessary, these can be made from regular operating records. *No documents beyond ordinary records for internal operation of the health department need be kept for supplying information necessary for grant-in-aid administration when a procedure similar to that described is followed.* Furthermore, some account is taken of person-

nel. It may be almost axiomatic that with the right kind of people on the job—people of competence and integrity, in reasonable numbers, having sufficiently varying professional backgrounds and adequate equipment with which to work—then a creditable performance can be assumed with a reasonable degree of confidence. However, to assure oneself on this point, he must begin by examining into the qualifications of the staff, but more especially into the personnel practices of the department under audit. In this way, he can determine whether the type of performance disclosed by the audit of service is likely to continue.

Throughout the auditing procedure, which should be integrated with regular consultation visits during the year rather than scheduled as a separate independent procedure, rapport is developed between the surveyor and the organization under review for, by this arrangement, the questioning which takes place is not a form of catechism but entirely a give-and-take discussion—a technique which engenders and fosters the spirit of coöperative endeavor.

At this point we are satisfied that, program audit will more nearly meet our needs than any scheme we have yet tried, and there is strong basis for feeling that state health agencies in turn can use it for reducing some of their present reporting requirements of local health units. Any records that are being kept locally for the sole purpose of accumulating information to be reported to someone else—whether a state or federal agency—should be scrutinized with a view to being eliminated. In all probability, if state personnel periodically audited programs according to the method which we have roughly outlined, they too, would be much better informed regarding those programs than when they rely upon reported statistics. Local health officers, as well, might advantageously utilize a similar technique

in checking the performance of the various members of their operating staffs.

By way of summary, may we repeat just two points which we hope have been made perfectly clear: First, program audit is not an instrument for research. From the plan, which must be approved before any funds are authorized, it must be decided whether the program is fairly well conceived. A program audit is designed merely to show whether the plan is being carried out faithfully and with a *reasonable degree of effectiveness*. On the basis of facts revealed by a program audit we believe that it is possible to judge accurately enough whether a program is static, going backward, or forward. Research is another matter, and usually has a set of requirements all its own. While it is recognized that important information of research value may be obtained from routine administrative records, generally speaking, research should be set up as a special project, circumscribed in scope and—for the most part—allowed to continue during only a limited period of time. No system of everyday operations should be loaded down with requirements keyed to research purposes.

Second, true knowledge of an operating program cannot be gained by a person at a distance in his own office. Statements in defense of any system of records and reports that indicate it can be done are apt to be misleading; furthermore, such practice is detrimental to good relationship between supporting and operating agencies. Perhaps the chief advantage of program audit is the fact that it provides an opportunity for representatives of these two positions to meet each other face to face at the scene of action.

In conclusion, let us look to the future. Although programs of health departments are still of limited scope, there has already evolved an extremely

complex scheme of records and reports. Not only does it consume the full time of a clerical force nearly one-fifth as large as the total complement of health workers, but also, in some instances, it demands as much as one-third of the effective working time of professional groups. This situation becomes truly alarming as we envisage the future,

which promises to bring in a multiplicity of new programs containing an infinite variety of personal services. As these "coming events cast their shadows before them" it becomes imperative that some sort of simplified administrative procedure be substituted for detailed reports. To meet this need, we offer you program audit.

The Evaluation of Local Health Work*

ROSCOE P. KANDLE, M.D., M.P.H., F.A.P.H.A.

*Director, Bureau of Preventable Diseases, State Department of Health,
Trenton, N. J.*

THE development of local health services so far and that proceeding under the stimulus of the Subcommittee on Local Health Units makes evaluation an urgent requirement. We need to know how well we have done the job so far. We must know that new units are being soundly developed. We must know that the scarce personnel now available are performing activities which are actually effective and efficient. This is the major responsibility of local health officers, directors of the division of local health services, and of state health officers.

Evaluation is a very broad field. It means stock-taking of resources, personnel, and efforts. It requires an analysis of problems and how well they are being met with the machinery available. Also, it must ask, as Dr. Allen Freeman frequently does, "How much does it cost?" It includes the knowledge of all the community efforts in the public health field and critical study of how well they are integrated or correlated. It is essential to intelligent program planning. It is the one excuse for reports and most records as discussed by Dr. Mountin and Miss Flook.†

Although there are many devices and methods of evaluation, there seem to be three principal types. The first is the study of some type of activity report, which should be a current and constant

process; the second is by the use of some type of check list, such as the *Evaluation Schedule* of the American Public Health Association, which should be used at fairly regular intervals; and the third is the formal survey which should only be used to meet special and well defined objectives. Each is dependent on the preceding method, as well as other sources, for basic data. Each is a valuable tool of the local health officer, director of local health service, and the state health officer when judiciously used.

It is commonplace to talk about using activity reports, yet I presume we all have been guilty of sending in the old Quarterly Activity Report without looking at it. The lack of critical attention has occurred at each of the way stations noted, namely, the local unit, the state local health service, and the state department, *per se*. Not too long ago I recall a well trained state records official spending several days correcting quarterly reports which were then transmitted up the line and carefully filed. I believe every local health officer at least deserves a letter about his report from his director of local health service. It requires only a few minutes to see if the local unit has been able to protect any babies that month, or if the expectant mothers are making more than one visit to the prenatal clinics, or whether the sanitarian got around to his water samples, or visited any rural schools. Likewise, it is of great significance for the local staff to pause long enough to see what their collective efforts have been able to accomplish—

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946.

† See page 1137, this issue.

was it 10 or 100 infants protected, or were 2 or 30 per cent of the restaurants visited?

Let us go back for a moment a step farther to the daily work sheets from which the activity report is usually tabulated. It pays a local health officer occasionally to find out who is doing what on his staff. His supervisors should be doing this, of course, in larger units, but sometimes it is a long while between definitive analyses. Since public health staff persons are subject to human frailties, an occasional carefully administered jogging or pat on the back is helpful and probably necessary. More fundamental, of course, is the analysis of these records side by side with the local problems. Significant advances are being made in facilitating this kind of evaluation by the use of punch cards in local health departments.

The use of a check-list or more elaborate inquiry form is also necessary periodically. The development of such an instrument is not simple. After nearly 20 years of growth the current *Evaluation Schedule* is recommended for use by the Committee on Administrative Practice. I admit to a prejudice in its favor but I believe the prejudice is based on having seen it effectively used on many occasions and by as many different methods. The *Schedule* has real limitations. It is not easy to prepare. The *Schedule*, *per se*, is not the important focal point, however, as we all know. It is the *evaluation process* that is useful to the health officer. The *Schedule* is designed to help evaluate the community-wide program. It would be possible, and at times possibly desirable, to develop such a device to apply only to the health department. This would facilitate the preparation of a single form which could be prepared by the local health officer, with copies to his state office, the U. S. Public Health Service, Children's Bureau, A.P.H.A., or anyone else. It seems necessary, how-

ever, to look at the entire community if good program planning and maximum effective action is to be possible.

We cannot discuss all the details of the use of the *Schedule* here, but a few principles can be outlined. The most important, I am sure, is participation by every member of the staff of the health unit, by each agency involved. Personally, I like to take the *Schedule* apart and give appropriate sections to the staff and to other agencies such as schools, tuberculosis associations, etc. For example, it has happened that this is the first time that an engineer or sanitarian has been asked not how many inspections but what is the status of the food control program. This is the fundamental extension from the activity report to the *Evaluation Schedule*—or the program audit which Dr. Mountin described. The participation of public health people in this type of searching for facts is the backbone of good public health work. Parenthetically I might say that the health officer's special part of the *Evaluation Schedule* is the section on the problem analysis and it does not help anybody appreciably for the *clerk* to complete it. The *Schedule* is, however, designed to measure the community program and the community must help prepare it and study it after grading if really effective use is to be made of it.

A second important principle in the *Schedule* is the dominant item idea. It is invaluable in orienting the health officer, the staff, the agency, and the community in the essential relative values in public health. You will recall that it is believed by the Committee on Administrative Practice that there are certain aspects of any health program so essential that if they are not being carried out adequately, the total program must be considered poor. For example, in milk control, one might have a very fine group of dairies with the usual controls but, unless most of

the milk is pasteurized, we could hardly consider the milk control program good. Or, in tuberculosis control we could scarcely feel that we had an effective program if most of the active cases were still at home.

A third basic principle is that the standards by which the *Schedule* is graded are based on actual *practice*. Roughly speaking the standards for poor is the lower quartile of *Health Practice Indices*. In other words, if an activity is not being performed better than the lowest 25 per cent of practice it is considered to be poor. Or if it ranks among the top 25 per cent it is considered good. Obviously the validity of these standards will increase as *Health Practice Indices* includes wider representation from all over the country. Practice as determined by preparing the *Schedule* can be compared to that in *Health Practice Indices* or a standard of practice within the state can easily be established if schedules are available from a significant number of areas.

The division of local health service, in order to provide leadership, to be of maximum assistance and to be assured that maximum public health protection is being afforded with the resources available, needs to have current reliable evaluation data on each local health unit. The *Schedule* seems to be the best device at present to secure this and, therefore, it seems reasonable to think that a copy of a completed *Schedule* should be in use in the Division of Local Health Service for each well established health unit in the state. It will be found to have a great variety of office uses and to make field work much more effective.

There are, of course, a great many instances in which more detailed evaluation is necessary than is suggested by either of the methods discussed so far. Either the activity reports or the *Schedule* will frequently suggest to the

inquiring health officer items on which more information is necessary. For example, if it is learned that 15 per cent of the expectant mothers are receiving public health nursing service it will be important to learn if they are the ones needing the service most. In addition to this type, however, there are 2 areas which are quite important but less often investigated. One is the cost. Cost studies in public health are not new.^{1, 2} Some groups of students of government are, however, critical of public health staffs for lack of cost data. These are not easy to determine but are certainly pertinent. Those items for which unit costs can be fairly accurately ascertained, such as laboratory tests or certain routine type visits, should be investigated. Unit costs of some bedside nursing visits can be determined. Costs have been studied at the rapid treatment centers showing a very wide range, and probably these often did not include all costs. We can learn from the techniques of hospital administrators. While cost studies are difficult, we cannot afford to neglect them and must continue to explore the problem.

Another important technique not adequately explored in public health is that of flow studies with regard to the use of referral agencies by the health department, and *vice versa*. A health department which rarely refers a case to another agency or to only one other, can hardly be said to be an effective social agency. The matter of the referral or use of consultation service within the health department itself can also well be studied. Health problems demanding a wide variety of skills and teamwork for their solution are the rule rather than the exception.

The final broad type of evaluation is the formal survey, usually done by a survey group outside the jurisdiction itself, in contrast to those discussed so far which are very definitely to be done by the local health unit. This fact that

the local unit does not prepare a survey constitutes a major weakness. Self evaluation is surely the most effective method. Occasions arise, however, which make the survey method useful, as for instance when a major reorganization seems indicated, or extensive inter-agency relationships are involved, or when there is serious disagreement as to overall public health problems. Such surveys are, of course, most commonly made by outstanding public health authorities, or a professional organization. The reports invariably require wide community support and understanding for their implementation. There is another type developing, however, which is of possibly greater significance to us here. Some state health departments with numerous well developed local units have found a need to use the survey technique. It is done by a team specially recruited from the state department staff, or by a field unit of local health service. It is, of course, merely an extension of the use of the field unit as described by Dr. Harry E. Handley in 1938.³ The survey team will usually use the *Evaluation Schedule* as a nucleus and extend its researches into time studies of the staff, costs, flow studies, and appraisal of inter-agency relationships, etc. The technique can

probably be of real value in the *development* of full-time local health service in areas now served by entrenched part-time service. It might be an equitable method of settling major disputes of personnel and subsidy. It should constitute an important resource in evaluating policies of state and local departments.

Evaluation of local health work then is an essential part and should be specifically incorporated in all health program planning. Its effective use is good preventive medicine against complacency and self-satisfaction. It should be carried on continuously by the use of activity reports and critical indices; at regular intervals by some such device as the *Evaluation Schedule*; and occasionally for definite, major objectives by the survey method. It is a responsibility of the local health officer, the director of local health services and the state health officer.

Penicillin in the Treatment of Infectious Bovine Mastitis*

C. S. BRYAN, PH.D., D.V.M., F.A.P.H.A.

Department of Surgery and Medicine, Michigan State College, East Lansing, Mich.

MANY laymen and veterinarians misunderstand the use of the udder infusions in the treatment and control of bovine mastitis since they assume incorrectly that all cows with udder trouble should be treated with these materials. Udder infusions are effective only against infection and are of *no value* where the cause is non-infectious in nature. In fact, the use of udder infusion in such cases may aggravate the trouble.

Cows that produce market milk must be healthy (especially free from udder infection), clean, and stabled in sanitary quarters if the milk produced is to be safe and of reasonable high quality. The presence of infectious mastitis in the lactating cows, and the lack of application of proper and adequate sanitary procedures in handling the milk, result in bacterial contamination of the milk. Everyone concerned (veterinarian, dairy farmer, milk sanitarian, and milk plant operator) must know something about the cause and the types of mastitis if the essential proper herd management procedures are to be applied in solving the mastitis problem of the individual herd.

WHAT IS MASTITIS?

Mastitis is a very general term that refers to any inflammation of the udder; such as the physiological

swelling or congestion at "freshening" or that resulting from udder or teat injuries, or it can be the pathological change in the udder tissue as the result of infection. In so far as the condition of the cow and/or her udder is concerned, the mastitis may be classified as acute or chronic.

ACUTE AND CHRONIC MASTITIS

Acute mastitis may be divided into acute local mastitis and acute systemic mastitis. In the acute local mastitis, the symptoms of swelling, pain, and the production of milk of abnormal physical appearance are confined to the udder. The cow is eating well, and has a good appearance except for the udder changes. The acute systemic mastitis is characterized by a visibly sick cow in addition to the symptoms in the udder. The acute local mastitis may progress in severity to develop into the destructive and oftentimes highly fatal acute systemic mastitis.

Chronic mastitis is usually characterized by the absence of any painful swelling of the udder and by the production of a decreased amount of milk of normal physical appearance. Therefore, a cow may be infected for periods varying from a few weeks to several years before having an acute attack, and before the owner may become aware of the presence of the disease. The chronic mastitis may "flare-up" and become either acute local or acute systemic in nature. If death of the cow does not occur and treatment is in-

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, on November 14, 1946.

stituted, the acute condition may abate and chronic mastitis persist. This change from chronic to acute mastitis and *vice versa* may occur irrespective of the cause of the disease.

NON-INFECTIOUS AND INFECTIOUS MASTITIS

Udder troubles may be classified as non-infectious and infectious mastitis from the standpoint of cause. Such non-infectious factors as chilling, bruising, and injury of the udder or teats, rough handling of the udder during hand or machine milking, and the adverse effects, in some cows, of irregular or incomplete milking may cause mastitis of an acute or chronic nature depending upon the severity of the non-infectious agent or condition. Further, the damaging effects of non-infectious mastitis may predispose the udder to infection by bacteria.

The streptococcus group of bacteria most commonly causes the udder infection of a chronic type, but at times the streptococci and usually infection by *Staphylococcus aureus*, *Corynebacterium pyogenes*, and/or *Escherichia coli* and other bacteria produce an acute mastitis.

THE PREVENTION, CONTROL AND TREATMENT OF MASTITIS

The available scientific data, substantiated by field trials, indicate that the successful program for the prevention and control of bovine mastitis must include the following items in the order presented. Any effort to change this order is doomed to failure.

A. Good, sanitary milking procedures:

1. Arrange and/or milk cows in following order: healthy, suspicious, and infected.
2. Discard the foremilk into a strip cup, exclude from supply all abnormal milk.
3. Wipe the udder of each cow with warm (120° F.) disinfectant one minute before milking.
4. Exclude infected humans from milking cows.

5. Dip teat cups of milker in disinfectant between cows (have milk tube valve in head of machine open).

6. The hands of person milking or stripping should be dipped in disinfectant between cows.

7. Milk each cow regularly, rapidly, and completely for udder health; employ a system of managed milking.

B. Good, sanitary herd management procedures:

1. Proper stalls for cows.
2. Prompt treatment of udder and teat injuries.
3. Clean and disinfect stalls upon removal of infected cows.
4. Keep barn and barnyard clean and dry.
5. Raise heifers as disease-free replacements.
6. Early removal of accessory teats.
7. Preferred source of herd replacements; a—home raised heifers, b—purchase of bred heifers, c—purchase of milking cows—test before purchase.

C. Early and accurate diagnosis:

1. Physical examination of each cow's udder.
2. Bacteriological test to determine if infection is present or absent.

The physical examination of the udder and milk is valuable in determining the clinical condition of the cow and her udder. This information is important when a final decision must be made concerning the disposition and treatment of the individual case of mastitis. However, bacteriological procedures must be applied to properly collected milk samples to make the specific diagnosis of infection—if the infectious bacteria are present—or to exclude infection and, therefore, suggest that the cause of the trouble is non-infectious in nature. In my opinion, the veterinarian and dairyman must know the cause of the mastitis before they can intelligently apply preventive procedures or specific curative udder infusion treatments.

D. Elimination by slaughter or complete segregation of infected cows with badly damaged udders.

1. Such cows usually do not respond to udder infusion treatments.
 2. This eliminates or confines the source of infection.
- E. Early and proper treatment.
1. A high percentage of cows, without marked change in the udder, recover by udder infusions.
 2. Udder infusions are of value only where infection is the cause of the mastitis.
 3. Control measures must accompany treatment or the recovered case may become reinfected.

The judicious use of the udder infusions in treating infectious mastitis must necessarily be accompanied by sanitary milking procedures and farm sanitation if the occurrence of infection is to be prevented; otherwise, the recovered case becomes reëxposed and reinfection may occur.

PENICILLIN LEVELS OF MILK FOLLOWING UDDER INFUSIONS

The concentration of penicillin required in the infected area depends on the susceptibility of the infecting organism. The strains of hemolytic staphylococcus of bovine (mastitis) origin, and the group B streptococcus (*Streptococcus agalactiae*) are practically all inhibited by 0.025 units of penicillin per ml. Thus a concentration of 1 unit per ml. of milk should give a safe margin for these organisms.

In 1945 Murnane⁴ reported relative to the units of penicillin in milk at different time periods following the infusion of 15,000 units per quarter into

cows in varying stages of lactation. These data, presented in Table 1, indicate the effective level maintained for a relatively long period of time.

EFFICACY OF PENICILLIN IN THE TREATMENT OF INFECTIOUS MASTITIS

When streptococcus and staphylococcus infected animals, without marked physical changes in the udder, are treated with either an aqueous or oil solution, the various investigators have reported recoveries (become free from udder infection) in approximately 50 to 90 per cent of the cases. More recently, mastics—a new penicillin medication form—have been used by us to treat a series of 82 cows with chronic streptococcic mastitis which upon physical examination were deemed suitable subjects for treatment. Seventy-six or 92.6 per cent of the treated cows became free from the udder infection while 6 or 7.4 per cent remained infected despite repeated treatment. These data indicate the value of penicillin in the treatment of infectious mastitis caused by organisms that are susceptible to penicillin; in addition, they show that not all cows considered as good subjects for treatment will respond to the penicillin therapy.

PENICILLIN IN HERD TREATMENT OF INFECTIOUS MASTITIS

The necessity for good management procedures in the herd undergoing

* Again treated as before.

penicillin udder infusion treatment is presented by the data of Table 2. In only one case, herd 2, did a treated and recovered case become reexposed and reinfected, whereas reinfection was the rule in the herds under poor herd management practices. The treated and recovered case must be protected from reexposure by good, sanitary milking and herd management procedures since the successful treatment does not impart any immunity to the animal. If this is done the udder infusion treatments, such as penicillin, can be a real aid to mastitis control.

SUMMARY

The successful prevention, control, and treatment of mastitis includes, in the following order:

1. Good sanitary milking procedures.
2. Good herd management procedures.
3. Early and proper diagnosis.
4. The elimination from the herd of infected cows with badly damaged udders.
5. Early and proper treatment, penicillin is effective in a large number, but not all, of

the cases of infectious mastitis caused by organism susceptible to penicillin.

Oral Environment and Fluorine*

GERALD J. COX, PH.D.

Corn Products Refining Company, Chemical Division, Argo, Ill.

FLUORINE AND DENTAL CARIES:

SOME SALIENT POINTS

THE history of fluorine† and dental caries begins with the discovery of fluorine in a fossilized elephant tooth by Morichini, as reported by Morozzo⁴³ in 1803. Nearly one hundred years later Eager²³ observed black teeth among natives of Pozzuoli, Italy. This condition was described by Black and McKay¹¹ in children of Colorado Springs and called "mottled enamel." Fluorine in the drinking water at the time of formation of the enamel was shown to be the cause of mottled enamel in 1931 by Churchill (reported by Theriault⁴⁹) and by Smith, Lantz, and Smith.⁴⁷

Armstrong and Brekhuis⁴ found the fluorine content of the enamel of 46 sound human teeth to average 111 p.p.m.; that of 39 carious teeth averaged 69 p.p.m. The difference of the means was 11.9 times its standard error. They also found³ that the fluorine content of mottled enamel ranged from 250 to 361 p.p.m., and that severe caries existed in some of these mottled enamel teeth. Caries, or at least a condition thus far not distinguished from caries, is frequently observed in teeth with mottled enamel.³⁶

Miller³⁷ markedly inhibited dental caries in the albino rat by feeding 250 p.p.m. of sodium fluoride in a caries

producing diet. Cox, Matuschak, Dixon, Dodds, and Walker¹⁹ reduced the incidence of caries in young rats by feeding their mothers rations containing from 10.3 to 41.2 p.p.m. of fluorine during pregnancy and lactation. The experiment of Miller³⁷ was one in *posteruptive* prevention of caries by a high level of fluoride feeding; that of Cox, et al.¹⁹ prevention by the traces of fluoride transmitted to the young by the mother only during the *period of formation* of the enamel and *prior to eruption* of the teeth.

Dean, Jay, Arnold, McClure, and Elvove²² observed a rate of 194 carious permanent teeth per 100 individuals in 243 children, 12 to 14 years of age, and of continuous residence in Galesburg, Ill., where the water supply had 1.8 p.p.m. of fluorine. They found a rate of 628 carious teeth in a comparable group of 291 children in Quincy, Ill., with 0.2 p.p.m. of fluorine in the water supply. It is of particular interest that they found a much greater reduction of the incidence of caries in the upper anterior teeth than in the molars. Dean and his coworkers extended their surveys with similar findings²¹ in other cities with a total of 7,257 children studied. Their observations have been confirmed by others in widely scattered parts of the world.

Volker⁵⁰ found that powdered human enamel showed a significantly diminished solubility at pH 4.0 after it was shaken for one hour with sodium fluoride solutions as dilute as 100 p.p.m. His data give positive evidence that reduction of caries by fluorine is due to reduced solution of enamel by acids

* Presented before a Joint Session of the Food and Nutrition and Dental Health Sections of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 14, 1946.

† "Fluorine" in dental caries literature never means elementary fluorine but the "fluoride ion" in solutions, or "combined fluorine" in solids such as salts or dental enamel.

produced by bacteria. Cox¹⁸ and McClure³⁴ found (a) that the fluorine content of human saliva is of the order of only 0.1 p.p.m., and (b) that it is not significantly different in the salivas of children from areas with low fluoride waters and those with fluorine in the water up to 1.8 p.p.m.

Cheyne¹⁴ made topical applications of 500 p.p.m. fluoride solutions at 3 month intervals to the deciduous teeth of children and reported an average of 3.09 new carious surfaces in a year as compared with 6.04 in a control group. Bibby⁷ applied 1,000 p.p.m. sodium fluoride every 4 months to the permanent teeth of children. In a year, 60 new cavities appeared in control teeth and 33 in treated teeth.

ORAL ENVIRONMENT AND DENTAL CARIES

Predecessors of W. D. Miller suggested that microorganisms were factors in dental caries but he was the first to give an effective presentation of facts to support what is now known as the "oral environment" theory of dental caries. Miller, an American dentist studying in Berlin, in 1882³⁸ announced the two essential parts of his chemico-parasitic theory, namely, that the decalcification of the teeth in caries is due to acids formed *in situ* by microorganisms and that the acids are formed from carbohydrates. In a series of papers, which were later summarized in a book,⁴⁰ he described the bacilli associated with caries and produced caries-like areas in extracted teeth immersed for long periods in fermenting mixtures of bread and saliva. It is important to note that Miller considered that he had not found all the factors in tooth decay as he wrote³⁹: "The extent to which any tooth suffers from the action of the acid depends upon its density and structure, but more particularly upon the perfection of the enamel and the protection of the neck of the tooth by healthy gums. What we might call the

perfect tooth would resist indefinitely the same acid to which a tooth of opposite character would succumb in a few weeks." This *opinion* is generally ignored by the extreme oral environmentalist who asserts that any tooth will succumb to caries; it is the best hope of the nutritionist, whether he believes in pre- or post-eruptive influences on enamel or both.

Since the time of Miller, bacteriologists have sought to identify organisms associated with caries. Some of the early workers who described *L. acidophilus* types were Goadby,²⁵ Moro,⁴² Howe and Hatch,²⁹ Rodriguez,⁴⁵ and McIntosh, James, and Lazarus-Barlow.³⁵ Those who isolated streptococci from carious lesions and assigned to them a causal rôle were Sieberth,⁴⁶ Baumgartner,⁶ Niedergesäss,⁴⁴ Hartzell and Henrici,²⁶ Sperling,⁴⁸ and Clarke.¹⁵

There has been considerable controversy over the relative contribution of lactobacilli and streptococci to the carious process. Bunting and Jay and their associates in a number of papers have shown the high correlation of counts of lactobacilli and *caries activity*. Jay³⁰ has said, "Many do not agree that causal relationship exists between the lactobacilli and dental caries. Regardless of this controversial point, these organisms afford an excellent means of estimating caries activity . . ." It is argued that streptococci are more active agents in caries since they are more frequently found in the advancing border of the carious process²⁶ and are more rapid acid formers.⁹

There have been attempts to immunize human subjects against dental caries by means of vaccines made from oral strains of *Lactobacillus acidophilus*. For example, Williams⁵² has shown that following the use of such vaccines, blood agglutinin titers were increased but only 5 of 20 subjects showed a significant reduction in salivary counts for lactobacilli. No changes were found in the

dental conditions in respect to existing cavities or in new carious lesions. There are apparently antibacterial substances in human saliva "which destroy, inhibit growth, or so change the organisms that they lose pathogenicity" as shown by Hill²⁷ and by others. These substances may or may not be related to caries immunity.

Kendall³¹ in 1910 introduced the term "aciduric" meaning "to endure acid" as being more appropriate than "acidophilic" when applied to organisms that can survive in media of high acid content. Gies and Kligler²⁴ considered the aciduric property to be one of the essentials of a caries producing organism, and Rodriguez⁴⁵ and McIntosh, James and Lazarus-Barlow³⁵ made survival at low pH the criterion by which to judge the relative caries producing power of an organism. By means of this hypothesis, streptococci, which relatively are weakly aciduric, were excluded from a causal rôle in spite of their continued existence in deep lesions where presumably low pH conditions should exterminate them. The aciduric hypothesis led to the adoption of media of low pH for study of bacteria associated with caries. Obviously this arbitrary procedure resulted in the suppression of streptococci and obscuration of their possible role in caries.

Bibby, Volker, and Van Kesteren⁹ found that the amount of tooth substance dissolved by oral bacteria was proportional to the amount of acid formed. This relation of *acidogenic* rather than *aciduric* power to the production of dental cavities is the more logical. Bibby, et al. also showed that (a) streptococcal forms are more numerous in carious lesions, (b) streptococci form acid much more rapidly than lactobacilli, and (c) lactobacilli probably form no more than 0.025 per cent of the total acid arising from carbohydrates due to organisms found *in saliva*. They pointed out that neutralization of acid

by dental tissues keeps the pH high enough for streptococci to survive.

Williams⁵¹ observed dense masses of bacteria on teeth and considered such plaques as essential in the initiation of caries. Black¹⁰ said, "The one thing necessary to the beginning of caries is the formation of such a gelatinous plaque in a secluded position where its acids may act . . ." Miller⁴¹ did not accept plaques as essential to his theory and pointed out that plaques frequently occurred where caries is seldom found and that he had found incipient caries with no plaque cover. Blayney, Kesel, and Wach¹² observed caries with some plaques but not with others and associated the presence of lactobacilli in the plaques with the occurrence of caries.

INTERIM SUMMARY

The following points are summarized from the foregoing considerations of both fluorine and oral environment in dental caries:

Excessive fluorine during the period of formation of the enamel causes mottled enamel.

The condition of unmottled enamel, with respect to caries is related to fluorine in that sound enamel has a fluorine content of about 111 p.p.m. and enamel from decayed teeth about 69 p.p.m.

The fluorine content of mottled enamel ranges from 250 to 361 p.p.m.

Teeth with mottled enamel decay.

Sodium fluoride, given to young rats as 250 p.p.m. in the food *after* their teeth are erupted, markedly inhibits caries activity.

Fluorine, as transmitted to rats through the placenta and the mammary glands before eruption of the teeth, causes a significant reduction in the incidence of caries.

The rate of incidence of caries in children is significantly lower in areas with up to 1.8 p.p.m. fluorine in the drinking water than in regions with fluorine of the order of 0.2 p.p.m.

The reduction of caries in man by fluorine in the drinking water is greater in the upper anterior teeth than in the molars.

Exposure of powdered enamel to fluoride solutions reduces the rate of solution of the enamel at pH 4.0.

The fluorine content of human saliva is of the order of 0.1 p.p.m. and is unaffected by the

fluorine content of the community water supply up to 1.8 p.p.m.

Topical application to human teeth of fluoride solutions of the order of 500 p.p.m. and over, results in a significant reduction in new carious surfaces.

The production of cavities in teeth is said to be caused by acids formed by bacteria thriving predominantly on carbohydrates.

The count of *L. acidophilus* in saliva is an index of caries activity.

There is no convincing proof that any organism or group of organisms is specific in the production of carious lesions.

Successful immunization of human subjects against dental caries by means of vaccines has not been achieved.

There are antibacterial substances in saliva.

The cavity producing power of micro-organisms is probably more related to their ability to produce acid than to survival in acid media.

IMPACT OF FLUORINE ON THE ORAL ENVIRONMENT THEORY

Fluorine was one of the factors in dental caries unknown to W. D. Miller.⁴⁰ However, the discoveries of the last ten years on the influence of fluorine on the course of dental caries in no way weakens the position of Miller, rather, it has made it more difficult to explain caries exclusively as independent of the tooth. Resistance to caries through nutrition is supported at least by the idea that caries-resistant teeth result¹⁹ when an optimum amount of fluorine is available during the formation of dental enamel.

With the advent of fluorine as an anti-caries factor the theories of cause of tooth decay should have been thoroughly reexamined and the action of fluorine studied from the many viewpoints. Unfortunately, because fluorides were known to be enzyme inhibitors and also retarders of bacterial development, the oral environmentalists early captured the field and bent fluorides to the purpose of proving rather than testing their theories. On the other hand, the toxicity of fluorides was against nutrition theorists and toxicity was emphasized by mottled enamel, a dystrophy displayed in the very tissue that a

fluoride prophylactist would venture to protect.

In the case of both oral environment and nutrition theories, the quantitative phase of fluorine has been too little noticed. The fluorine content of waters that reduce the incidence of caries in children is of the order of 1 p.p.m.²¹ Wright⁵³ found that a minimum concentration of 10 p.p.m. of fluorine affected acid formation from sucrose by a streptococcus. Bibby and Van Kesteren⁸ concluded that fluorine concentrations of less than 1 p.p.m. "limit acid production by bacteria but concentrations in excess of 250 p.p.m. are needed to affect bacterial growth." It is to be noted that these are fluorine concentrations in continuous contact with the bacteria and not those of intermittent exposure as in the act of drinking of water. Consequently, it is not likely that the fluorine in drinking water up to 2 p.p.m. would retard acid formation by bacteria.

A generally accepted and an essential part of the oral environment theory of caries is that the acid which decalcifies teeth is derived from carbohydrate. Miller's⁴⁰ observations were made using bread as a source of carbohydrates. As it is simpler to prepare sugar media for culture of bacteria, it is possible that attention has been focused on the sugars as the "cause" of caries.

The albino rat is unique in that it does not develop dental caries after long consumption of diets containing glucose, sucrose, lactose, maltose, or corn starch at a level of two thirds of the ration.³³ Caries does not result in white rats in a year on a 53 per cent sucrose diet with lactobacilli forced into their mouths thrice weekly.³² Yet if caries is initiated in the albino rat and fermentable carbohydrates are supplied, the cavities increase in size but not in number.^{16, 28} These observations suggest that the process of *initiation* of caries may be different from that of *increasing* cavity

size. Such a hypothesis differentiating initiation from promotion of caries may be useful in clarifying the influence of fluorine in the prevention of caries since the influence of that element seems to be absolute prevention at a given site rather than a factor which slows the rate of cavity development. If this should prove to be true, then by means of fluorine, teeth can be formed that will not decay under the influence of bacteria and carbohydrate. Fluorine may also act to slow the rate of cavity development because it lowers the rate of solution of the enamel.⁵⁰

It is unlikely that fluorine can be the salivary antibacterial substance of Hill²⁷ since it is only present to the extent of 0.1 p.p.m.^{18, 34} It is also unlikely that the fluorine of saliva can diminish acid formation by bacteria as it is below the levels found by Wright⁵³ and Bibby and Van Kesteren⁸ to affect acid formation. Also, a difference in fluorine content of the salivas would necessarily have to exist to invoke an acid-inhibiting theory that the reduction of caries incidence is related to the fluorine in saliva.

Dean, et al.²² noted that the count of *L. acidophilus* in the salivas of Galesburg children—1.8 p.p.m. fluorine in the water—was lower than in the salivas of Quincy children with 0.2 p.p.m. fluorine. This diminished count according to Bibby and Van Kesteren⁸ would require a concentration of 250 p.p.m. and could not therefore be due to the fluorine of either the intermittently imbibed water or the continuously present fluorine of the saliva. The only concentration of fluorine in the mouth high enough to retard bacterial growth is in the enamel and it would seem illogical to invoke fluorine in such an immobile state to be effective. It would seem that fluorine could only retard the activities of bacteria by entering into their cells.

It is of interest in the relation of

fluorine to plaques and caries that Day²⁰ found plaques on the teeth of 309 of 314 children of whom 74 per cent had mottled enamel and an incidence of only 0.62 carious cavities. This indicates that certain plaque organisms can exist in contact with a high content of fluorine. The organisms in these plaques, however, may not have been those which are associated with dental caries.

It is to be noted that the concentrations of fluorine used in topical applications^{14, 7} have been of the order of, or in excess of the 250 p.p.m. stated to retard bacterial development.⁸ It is therefore possible that the fluoride solutions have had a sterilizing influence on the flora of the teeth. If bacteria in undetected beginning caries were destroyed, a reduction later in new cavities would possibly result. If a control series in these experiments with a nonfluoride bactericidal agent had been used, the specific action of fluorine would have been tested. The value of topically applied fluorine in explaining the true action of lowered incidence of caries in areas with fluorine containing waters is therefore questionable.

Dean, et al.²² noted that caries in the upper anterior teeth was prevented much more by fluoride waters than caries in the molars. Volker⁵⁰ was the first to suggest that this phenomenon was because of greater contact of the anterior teeth with water in the act of drinking. Anderson has described mottled enamel among Chinese¹ and dental caries.² (Dr. Anderson, in a personal communication, has stated that the two reports dealt with the same group of Chinese.) In the *permanent* teeth the pattern of decay was that observed by Dean, et al., with only 4 of 3,211 upper incisors affected. But in the *deciduous* dentition the rate of decay of anterior teeth was at a much higher rate than in the permanent teeth and was not different from that of the molars. This would imply that the con-

tact with drinking water is not the true explanation of the low rate of caries in anterior compared with posterior teeth.

Unfortunately the reports of Dean and his coworkers and of Anderson do not show the incidence of decay in specific areas of the teeth. It may be suspected that decay is restricted to pits and fissures of the molars and that the lateral surfaces would be as free of caries as are the upper incisors. If this were found to be true in future studies, the better explanation of this aspect of fluorine prevention of caries would be from preëruptive influences. The oral environmentalist explains the occurrence of caries in well recognized vulnerable areas such as in the pits and fissures of molars and in inter-proximal sites as due to retention of food. This explanation is satisfactory for the promotion of caries once initiated but fails in the face of the erratic incidence of decay in adjacent teeth. Bödecker and Ewen¹³ reported: "An examination of 516 full mouth x-rays, selected at random showed 179 carious lesions affecting only one of two closely contacting teeth. This condition (unilateral caries) indicates that food retention, bacteria, and saliva cannot be the *sole* factors in dental destruction." They indicated belief in variable resistance of the teeth. Such variable resistance could well be due to variations in available fluorine during formation of the teeth. If it were shown that adjacent teeth have different levels of fluorine plus the related resistance to caries this situation could only be explained by preëruptive influences including variations in the fluorine supply.

Cox¹⁷ discussed fluoridization of community water supplies with seasonal variation according to water consumption so as to provide for a constant year round intake of fluorine. The reason for such constancy was to maintain as high a level of fluorine intake as possible without causing mottled enamel, with the expectation of forming enamel with

the greatest resistance to caries. Other proposals to add fluorides to water, such as those of Ast,⁵ provide for a year round level of 1 p.p.m. of fluoride. This method provides for a constant level of fluorine for oral environment but a variable amount from the viewpoint of nutrition. This method of providing 1 p.p.m. of fluorine is being applied now in several communities.

One of the precepts of current studies⁵ on the addition of fluorides to community water supplies is that a period of years must elapse before results can be known. Certainly this is not true if the action of the fluorine is on the oral environment, and reports dealing with that phase should soon be forthcoming. But if the action is through formation of caries-resistant enamel, that is, through a nutritive mechanism, the results cannot be known for years.

It is not necessary to wait for the outcome of experiments on human populations to determine the detrimental effects, if any, of adding fluorine to water supplies. The field pioneered by Dean, et al.²² remains almost unexplored as to other than dental effects of fluorine and proper investigation can be made at once on populations with long exposure to fluoride waters.

Dean and his associates confined their attention to children of continuous residence in the communities they examined. If they had included migrants at various ages, they could have cast much light on the permanence of fluorine in preventing caries or, in other words, could have determined whether it is a matter of oral environment or of nutrition. Such studies should include the examination of children moving into and out of communities where experimental additions of fluorine to water supplies are being made.

The mechanism by which fluorine protects teeth remains unknown. It appears, at least in the anterior teeth, to prevent caries in the sense that no decay appears.

This would seem to indicate that it prevents initiation of decay. Once caries is initiated it may progress less rapidly in teeth with increased fluorine, but the fact that mottled enamel teeth become carious^{34, 36} indicates that the fluorine content of the teeth acts neither to inhibit bacterial life nor solution of the enamel by the acids formed by micro-organisms.

It would seem wise to return to the view of Miller³⁹ that structure of the enamel is a factor determining whether or not a tooth surface will become carious. The structure, so far as it is influenced by fluorine, should be viewed as acting to resist caries either because of a part played by fluorine in its make-up or by an effect of fluorine on the cells that deposit the enamel. In the latter case, the increased fluorine content of the enamel would be only adventitious.

It is fortunate for oral environmentalists that they are divided in general in their philosophy only as to the identity of the microorganisms that "cause" dental caries. If an organism specific for dental caries exists, immunization against the disease might be possible if such immunity could be induced upon the oral cavity. Such immunization has not been achieved and hence the matter of a specific organism remains only of academic importance.

It is unfortunate for the millions of sufferers from dental caries that the oral environmentalists prefer their unanimity of opinion that any tooth will decay if only carbohydrates and acid-forming bacteria are in contact with it, and reject the viewpoint that resistance to caries can be built into the enamel by nutrition. Their assurance, based largely upon observations in the Petri dish, blocks proper collection and analysis of data on dental caries, such as the frequency of attack in specific areas. Since bacteriologists can most readily collect saliva and plaque specimens from human mouths, they have not made large use

of experimental animals. Therefore, they tend to reject the evidence from the albino rat that initiation of caries may differ in its mechanism from further development of a cavity.

It is unfortunate that nutritionists are divided in their philosophy in the field of dental caries. A major schism exists in the matter of pre- and post-eruptive effects of nutrition on dental caries. This is of primary importance as affecting the way in which fluorine as well as calcium, phosphorus, and vitamins A, C, and D are applied in relation to dental caries. Nutritionists seem content to accept and analyze the data of dental caries on a whole mouth basis in the manner of the oral environmentalist rather than by the area by area method that challenges the theories of both these opposing groups. Nutritionists have not yet declared fluorine an essential factor in caries. This withholding of opinion is undoubtedly because of the prior knowledge of its toxicity, uncertainty of the mechanism in its prevention of caries, and, also because teeth themselves may not be regarded as essential. But it is fortunate for the millions of sufferers from dental caries that division of opinion exists among nutritionists since from such conflicts and doubts come the stimuli for research that will eventually lead to methods to prevent, as well as control, dental caries.

Large-scale experiments are now being conducted in several localities on the effects on dental caries of the addition of fluorine to the community water supplies. These additions are being made on the oral environment basis of a uniform level throughout the year, and the level is held low because of fear of producing mottled enamel and other possible injuries. Dosage cannot yet be made on a nutritional basis, except by guess, because the necessary knowledge is lacking on (a) the optimum requirement for fluorine and (b) the variability of the intake of drinking water by

children in relation to season. The constant level procedure of the fluoridization of water supplies, however, will provide a test of the general effectiveness of fluorine in the prevention of dental caries. It is to be hoped that those in charge of the studies (a) will report the data on frequency of caries in specific areas of the teeth and not on a whole tooth basis, (b) that the original data will be made available, and not suppressed by resort to expression by rates, and (c) that especial attention will be given to individuals who have varying degrees of exposure to fluoride-bearing waters. Such data will aid in the decision as to the degree in which fluorine acts as an element in nutrition and in oral environment.

If it should be shown eventually that fluorine acts through channels generally viewed as nutritional, this finding should not be permitted to cause acceptance of all other factors that may be related to dental caries through nutrition, nor should it be allowed to diminish the importance of the oral environmental factors in development of cavities in teeth that are not conditioned to resist dental caries.

Signs of Progress in Dental Health*

ALLEN O. GRUEBBEL, D.D.S., M.P.H., F.A.P.H.A.

Executive Secretary, Council on Dental Health, American Dental Association, Chicago, Ill.

IT is considered good practice to pause occasionally in the performance of our duties in order to take stock of our achievements or failures. When we make such an appraisal of efforts to prevent or control dental diseases, or to find a means of providing dental treatment for all persons who need dental care, it is easy to become skeptical of our chances to achieve these goals in our time. The almost universal distribution of dental disease in the population, and the limited preventive and treatment facilities available to combat these diseases, are not conducive to a high degree of optimism in the search for a satisfactory solution to the problem.

On the other hand, an evaluation of progress and an estimate of future achievements can be regarded in a more favorable and hopeful light when we take into account the relatively short period of time during which the dental and public health professions have studied and attacked the dental disease problem from a public health point of view. It has been only during recent years that we have begun to study the occurrence of dental disease according to accepted epidemiological standards, and have attempted to apply public health methods to the problem. While the accomplishments of the last few years are admittedly of modest proportions, the outlook for greater achievement in the years immediately ahead is certainly more favorable than it was 10

years ago. The extent of our progress during the next decade will depend in large measure on how fully we use our available facilities and knowledge, as well as on the development of new resources.

The American Dental Association, through its Council on Dental Health, unquestionably can make a contribution in this direction. The American Dental Association and its component societies are in position to carry out many activities that are important adjuncts to the total effort in dental health promotion and which could not be as readily undertaken by other agencies. For example, no other organization has an equal opportunity, or perhaps an equal responsibility, to conduct a longitudinal study of the dental health problem, to create an informed dental profession in matters related to dental health advancement, and to secure the coöperation of individual dentists and dental societies in community health planning. The Council on Dental Health has recognized the need for such action and is now engaged in the development of several projects designed to utilize more fully the resources of the dental profession in the promotion of dental health.

DENTAL HEALTH WORKSHOP

There has been much discussion in recent months about plans which might be adopted nationally to provide a wider distribution of health care. At the moment it seems likely that proposals to expand local health services will receive more general support than will a nation-wide insurance plan. It is also

* Presented before the Dental Health Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1946.

quite likely that the provisions of S.1099, which was introduced in the last Congress, may be adopted eventually in either a separate bill or as a part of other legislation. If funds become available to expand dental services for children, and to develop and maintain educational programs and demonstration projects, a mechanism will be needed to secure the support and advice of local agencies. Obviously, state and local councils on dental health should participate in the formulation of community dental health plans.

The A. D. A. Council on Dental Health intends to sponsor a series of workshops as a continuing activity, so that individual dentists and state and local councils on dental health may have an opportunity to consider the dental health problem in their own areas, and so that the dental profession may be in a better position to provide technical advice. Workshops have been used successfully for a number of years in the educational and civic improvement fields. In general terms, the purpose of the workshop is to bring together a group of individuals who are interested in solving a particular problem so that they can examine objectively all the facts which make up the problem and adopt recommendations for a plan of action. Usually a workshop is conducted for a period of one or more weeks, but since dentists would probably find it impossible to leave their offices for such a lengthy stay, the dental health workshops will be concentrated into three day meetings.

The three day conference will be divided into three major sessions. On the first day five or six speakers will present basic facts objectively; factual data will be outlined without an expression of personal opinion as to how the problem should be solved. The second day will be devoted to group discussions which would permit a more intensive examination of (1) the possi-

bilities of utilizing and expanding dental personnel and ancillary aids, (2) the establishment of desirable features of a community dental health program, (3) the establishment of responsibilities of groups and agencies for the promotion of dental health, and (4) recommendations for experimental or demonstration projects.

Through this procedure the members of the dental profession will have an opportunity to examine critically, through group discussions, a number of important questions, such as:

1. Is it desirable to increase dental personnel so that all persons who need dental service will receive it?

2. What methods should be adopted to secure an even geographic distribution of dentists in relation to the distribution of the population?

3. Should the Alabama plan of providing scholarships for dental students from each county be adopted by all states?

4. To what extent should the number of hygienists, technicians, dental nurses, and assistants be increased?

5. What should be the long-range objectives of a community dental health program?

6. What basic plans should govern the establishment and maintenance of dental health programs for the public?

7. Should a community dental health program include provisions for dental care?

8. If so, who should receive dental care in an organized plan? How should a dental care plan be financed? Should the dental care plan be limited to indigents? What criteria should be used to establish a means test?

9. What are the responsibilities of the dental profession in the organization and maintenance of a community dental health program?

10. What are the responsibilities of the city and county governments in supporting a dental health program?

11. What are the responsibilities of public school systems in promoting dental health?

12. What responsibilities can be delegated to lay committees?

13. What types of experiments or demonstrations conducted as community projects would aid in the adoption of methods for (a) preventing dental diseases, (b) educating the public in dental health matters, and (c) providing dental care for a larger number of people?

When the dental profession, through objective discussion and deliberation, has had an opportunity to study these questions, it should be in a better position to assist other health agencies in the establishment of community health programs. The Council on Dental Health believes that a continuing series of dental health workshops will prove to be very important and fruitful activities.

ANNUAL CONFERENCE OF STATE COUNCILS

As a projection of the workshop idea, conferences of state councils on dental health will be held during the annual meetings of the American Dental Association. Approval has been secured from the officers of the A. D. A. for the organization of annual conferences to be patterned after the State Officers' Conferences. These sessions will be planned to present and discuss the actions and findings of state councils on dental health. Through this procedure the state and component societies will have opportunities to exchange opinions and to enter into free discussions of the policies of the American Dental Association, as well as the national aspects of dental health planning.

The first annual conference of state councils will be held in Boston during the 1947 annual meeting of the American Dental Association. There is every reason to believe that the series of workshops and the annual conferences of councils will establish a mechanism for creating an informed dental profession and for securing active participation in dental health promotion.

SCHOOL DENTAL HEALTH MANUAL

The Council on Dental Health has recently prepared a manual to be used as a guide in the establishment and maintenance of dental health programs in elementary and secondary schools. This manual has been developed in

response to a considerable number of requests from members of state councils on dental health. The A. D. A. Council was informed that local dental groups could be of more direct service as members of school and community planning committees if reference material were made available to guide them in recommending policies and procedures for school dental health programs. The manual outlines accepted school health practices, organizational and administrative technics, and the responsibilities of dentists, school officials, health officers, and nurses in organizing and conducting school health programs. The manual has been submitted to public health dentists and other health workers for comment and criticism. The final revision is now being printed and will be available for free distribution soon.

DENTISTRY'S PARTICIPATION IN THE WORLD HEALTH ORGANIZATION

The International Health Conference held in New York City in June, 1946, resulted in a recommendation to establish a World Health Organization under the auspices of the Economic and Social Council of the United Nations. A number of technical advisers to the United States delegates were selected from the personnel of the Department of State, U. S. Public Health Service, American Medical Association, American Pharmaceutical Association, Bureau of the Budget, Federal Security Agency, and National Nursing Council.

While it may not have been practical to include at least one dental representative as an adviser to the United States Delegation attending the International Health Conference, it would be desirable to provide for dental representation during conferences of the World Health Assembly in the future. This would seem valid in view of the fact that dentistry is an integral part of any general health service and that many of the health problems which will come up

for discussion will encompass dental implications. This assumption can be applied specifically to the functions of the organization dealing with:

1. the promotion of coöperation among scientific and professional groups which contribute to the advancement of health,
2. the promotion of maternal and child health and welfare,
3. the promotion of research in the field of health,
4. the promotion of improved standards of teaching and training in public health, medicine, and related professions,
5. the study and report, in coöperation with other specialized agencies, of administrative and social technics affecting public health and medical care from preventive and curative points of view, and
6. the creation of an informed public opinion among all people on matters of health.

In recognition of the fact that the prevention and control of dental diseases constitute an essential part of a total health program, and therefore, that competent dental representatives should be available to the participants in the World Health Assembly, the American Dental Association has recommended the appointment of dental representatives from each of the member nations as dental advisers to the delegates.

This recommendation will be filed with the officials of the World Health Organization and the officials of the United States Government within the very near future.

DENTAL HEALTH GOALS

The deliberations of the Council on Dental Health have revealed that the objectives of the American Dental Association for promoting dental health have not been revised since the adoption of the recommendations proposed by the National Health Program Committee in 1939. The Council has decided that much could be gained by a restatement of the objectives based on the conditions and trends of today. This has resulted

in the following statement of goals approved by the House of Delegates during the meeting in October 1946:

1. The prevention of dental diseases through the application of preventive technics as soon as they are demonstrated to be scientifically valid; the support of intensified dental research with adequate funds, personnel, and facilities.
2. The control of dental diseases by the expansion of community dental programs, integrated into the general health program, to provide every child with dental care and dental health education, regardless of income or location. These programs should be maintenance programs centered on the control of the annual increment of new dental diseases in children.
3. The provision of additional facilities and uniform standards for dental care by making dental services available in hospitals and health centers for inpatients and outpatients.
4. The recruitment of an annual enrollment of dental students equal to the capacity of all dental schools to increase the number of qualified dentists.
5. The adoption of measures to make dental practice in smaller cities and rural areas more attractive and rewarding in order to secure a better distribution of dentists.
6. The employment of dental hygienists as ancillary aids to the dentist; the provision of adequate training courses and training facilities for dental hygienists to prepare them as ancillary aids within prescribed legal limitations, and additional courses for those who desire to qualify for positions in public health departments and schools.

The statement dealing with the approval of dental hygienists as ancillary aids represents the first official action of the American Dental Association in recommending that suitable dental hygienist practice acts be established in all states.

DECENTRALIZATION OF AUTHORITY

It has been the common experience of dental health workers that the use of a means test to determine eligibility for dental service at public expense almost always becomes an issue in planning for

community dental health programs. Congress is being confronted with the same question in considering legislation which provides for grants-in-aid to the states. It will be recalled that the Taft Bill, S.2143, specifically required the inclusion of a means test in the approval of state plans. The Children's Bureau Bill, S.1318, specifically provided that a means test should not be used in making health services available to mothers and children in programs financed by funds under this Act.

For a number of years the American Dental Association has maintained that the community in all cases shall determine the methods for providing service within its area. In further support of this policy, the American Dental Association recently reaffirmed its stand by adopting a resolution providing that the decision on the employment of a means test in public health programs should be delegated to the state or community and should not be incorporated into federal legislation.

AUTHORITATIVE DENTAL INFORMATION

For a number of years dentists have commented on the many inaccurate and misleading statements on dental health matters which appear in public school textbooks. Frequently textbooks contain information directly at variance with that which appears in health education literature distributed by the dental profession. In order that this situation may be remedied as far as possible, the American Dental Association intends to augment its services to publishers by employing a competent dental health education specialist who will be assigned the task of editing and evaluating the dental context of publications for school children.

REMUNERATION FOR PUBLIC HEALTH DENTISTS

Realizing that the effectiveness of dental health programs administered by

official health agencies will depend in large measure on the caliber of public health dentists employed by those agencies, the Council on Dental Health has been deeply concerned by the fact that a large number of qualified public health dentists have resigned their positions with state and municipal health departments. There can be no question that the chief reason for these resignations has been the opportunity for more adequate remuneration in other fields. In an effort to correct this situation, The Council on Dental Health will attempt to secure the assistance of state dental societies in taking suitable action, through legislative measures if necessary, to obtain higher rates of pay for dental positions in state and local health departments.

HEALTH PRACTICE INDICES

The Committee on Administrative Practices of the American Public Health Association publishes a record of public health practice which is compiled from evaluation schedules submitted by local health officers. It is unfortunate that the accomplishment of workers in the dental health field are reported so ineffectively in these *Health Practice Indices*. Dental health activities cannot be judged accurately nor can their effectiveness be fairly measured by the presently used appraisal forms. The Central Office of the American Public Health Association has recently invited the A. D. A. Council on Dental Health to suggest an improved method of recording activities and results. The Council believes that this matter should be referred to public health dentists, and is therefore requesting the Dental Health Section of the American Public Health Association and the American Association of Public Health Dentists to assist in the adoption of recommendations for improving the dental health evaluation schedule for use in the study and appraisal of community health programs.

CONCLUSION

The above considerations outline the current actions and proposals of the Council on Dental Health. There is every reason to believe that, if the projects prove as successful as the Council hopes, the dental profession will be taking increasing interest in utilizing more adequately all of the available resources toward the promotion of dental health.

An Epidemic of Diarrhea in a New-Born Nursery Caused by *Pseudomonas aeruginosa**

CHARLES A. HUNTER, PH.D., F.A.P.H.A., AND
PAUL R. ENSIGN, M.D., M.P.H., F.A.P.H.A.

*Director of Laboratories, and Director, Division of Child and Maternal Health,
State Board of Health, Topeka, Kans.*

THIS report deals with an epidemic of diarrhea in infants that occurred in 1945 in the St. Rose Hospital (135 beds) at Great Bend, Kans., (10,000 population). The State Board of Health was notified of this epidemic on October 1. Investigation revealed that there had been occurrence and recurrence of diarrhea in the nursery and in infants dismissed from the nursery since June. Information was also obtained that there had been cases of diarrhea in the community and neighboring community for several months.

There were 24 infants who had either developed this disease in the hospital nursery, or had developed it after leaving the nursery, and then had returned to the hospital. In these 24 cases, there were 9 deaths. During this period of time there had been 278 births in the hospital.

Out of the 24 cases, considered in this report, 15 developed in the nursery, while 9 cases had been discharged from the hospital and returned. Of these 9 cases, 7 gave history of contact with a case of gastroenteritis at home; one returned to the pediatric ward because of feeding difficulty and 7 days later developed diarrhea, simultaneously with

the development of several cases in the nursery. The ninth case developed symptoms the day it left the hospital. A total of 19 probably contracted the disease in the hospital.

Diarrhea was the first, and often the only symptom, which might vary from a few soft frequent stools to extreme watery ones. The next most common symptom was vomiting, then dehydration, cyanosis, collapse, pain and fever, in that order. In 3 infants who died, early and extreme setting of the muscles in rigor mortis occurred. In many of the cases, diarrhea seemed to be recurrent over periods of time as great as 6 weeks, just as it was in some of the adult cases. The period of incubation varied from 1 to 7 days, most commonly 6. Only one case had an onset less than 4 days after birth; the onset in this case was 3 days.

From the epidemiological study the following points can be noted:

1. There were 6 outbreaks in the nursery with the development of from 1 to 6 cases in each outbreak.
2. These outbreaks were separated by periods of 15, 7, 49, 31, and 10 days.
3. In each outbreak, all the primary cases in the nursery occurred in one or two consecutive days. There were no secondary cases except that possible August outbreak.
4. Prior to every outbreak in the nursery, except the one in August, one mother or nurse on the obstetric floor developed the disease. In the August and October outbreaks, mothers

* Presented before the Laboratory Section of the American Public Health Association, at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1946.

had had the disease shortly before entering the hospital.

5. In every case where the mother had had the disease, her infant developed it.

6. One mother who did not have diarrhea came from a family in which two children did.

7. Several cases of gastroenteritis developed in other parts of the hospital, in medical, in pediatric, and surgical cases, and in 24 nurses and Sisters.

The hospital nursery had been very crowded of necessity, housing three times the number of infants it was built to accommodate. A proportionately large number of premature infants was in the nursery. A shortage of professional personnel existed. Consequently, there were some breaks in technic, but they were not gross breaks which would explain the epidemic.

The nursery outbreaks can be explained on the basis of secondary infection from infected mothers or nurses. It was proved that they were carriers of the organism causing the infection. The only condition which would cause such a large group of carriers is the ingestion of a contaminated food or water.

In addition to the infected mothers or nurses, there were several hundred cases of diarrhea in the community (histories were obtained on more than 400 which occurred between July 1 and October 15), and several cases occurring in outlying communities. The hospital, the city, and the outlying communities, had separate water supplies.

The only foods common to the hospital and city, which were not cooked before use in the hospital, were bread, lettuce, cold meats, and milk. The only persons who developed diarrhea in the outlying communities were using pasteurized milk from a dairy in Great Bend which also supplied the hospital. Only 21 of the 24 mothers could be contacted, but the one food all 21 used at the hospital was milk. Two of these developed diarrhea before entering the

hospital, but they bought milk from the same dairy.

From an epidemiological standpoint, a contaminated milk supply which had never been adequately controlled was the source of the infection. Milk for 90 per cent of the community came from 2 dairies which was labelled pasteurized milk. Inspection revealed both to be filthy, filled with flies; to have dogs in the milk room; to lack handwashing facilities; to have dust blowing in; to have no recording thermometers on the pasteurizing vats, and in one dairy a rag had been tied over a leak in a water pipe directly over the cooling coils. From this rag, water dripped into the pasteurized milk. *Pseudomonas aeruginosa* was isolated from the water dripping off of the rag. A heavy collection of milkstone on the pipes testified to the fact that they had not been properly cleaned for months. The bacteriological examination of the milk which consisted of the standard plate count, microscopic examination, coliform determinations, and phosphatase tests showed that more than 22 per cent of the samples of pasteurized milk from plant A had a standard plate count of over 3,000,000. Pasteurized milk from plant B had an average Standard plate count of 110,000. The phosphatase tests showed that 7 per cent of the samples from plant A were insufficiently pasteurized, and 23 per cent of the samples from plant B were not sufficiently pasteurized.

There were three different sources of water for the community; hospital, city, and private wells. The hospital had its own water supply and bacteriological examinations showed the water to be free of coliform organisms and *Pseudomonas aeruginosa*.

The city water supply (17 samples) did not show the presence of coliform or *Pseudomonas aeruginosa*. It is chlorinated continuously and tested regularly under the supervision of the

State Board of Health. It is estimated there are some 1300 private water supplies in Great Bend. Upon inspection by the sanitary engineers, none were found cross-connected to the city water. Seventy-two samples of water from private wells were examined and coliform organisms found in 16 of them. *Pseudomonas aeruginosa* was isolated from 4 wells.

The bacteriological study of the cause of illness and deaths of infants in the St. Rose Hospital, Great Bend, was started on October 1, 1945. A complete laboratory was set up in the hospital and 3 bacteriologists from the State Public Health Laboratories were assigned to study this epidemic. Stool specimens were obtained from all sick and some normal infants; from hospital nurses and employees; from mothers, and from residents of Great Bend that were sick or had recently been sick. Rectal swabs were used to collect the specimens except in some cases of the infants. The stools were plated directly on SS agar, MacConkey's agar, and desoxycholate agar. Tetrathionate broth and Selenite F broth were also used as enrichment media. All suspicious colonies were fished off into Kligler iron agar. These cultures were then sent to the Central Public Health Laboratories, Topeka, where complete study and identification were made.

Because of the clinical symptoms of the disease in some infants, and of the history of a sick father who returned by airplane from overseas, efforts were made to isolate all types of organisms, even *Vibrio comma*. Although *Pseudomonas aeruginosa* was isolated from the first case seen on October 1, it was difficult to believe this was the etiological agent, therefore, every effort was used to isolate all other possible organisms. Streptococci, both aerobic and anaerobic, were looked for in addition to the above mentioned group of organisms. Besides isolating *Pseudomonas aeruginosa* from

the infants, it was also possible to extract pyocyanine from the stools. More than five hundred stool specimens were examined.

Summary of Bacteriological Examinations

1. Infants under 2 years of age.....	38
<i>Pseudomonas aeruginosa</i> isolated.....	24
2. Infants followed clinically.....	24.
Number studied bacteriologically.....	9
<i>Pseudomonas aeruginosa</i> isolated.....	9
3. Normal infants studied.....	13
<i>Pseudomonas aeruginosa</i> isolated *.....	5
4. Autopsies on infants.....	2
<i>Pseudomonas aeruginosa</i> isolated from liver, spleen, gall bladder, and intestines.....	2
5. Rectal swabs on nurses and hospital employees	103
<i>Pseudomonas aeruginosa</i> isolated.....	16
<i>Eberthella typhosa</i> isolated.....	1
<i>Shigella alkalescens</i> isolated.....	2

* Four of the 5 infants became sick later and 1 left the hospital and could not be followed, but *Pseudomonas aeruginosa* had been isolated from the mother.

In addition to the results given above, a large number of *Proteus* and *Salmonella*-like cultures were isolated which were classified as belonging to the paracolony group. More than seven hundred cultures were studied. The identification consisted of cultural, biochemical, and typing for antigenic characteristics.

It is interesting to note that nurses in the nursery and pediatrics were carriers of *Pseudomonas aeruginosa*. Another finding of interest was the isolation of *Eberthella typhosa* from one of the nurses.

TREATMENT

The treatment before isolation of the organism had consisted of penicillin, transfusions, parenteral fluids, and sulfa drugs; the last two were the most effective. Following isolation of *Pseudomonas aeruginosa*, a review of the literature revealed that it produced small amounts of hydrocyanic acids. It was conceivable that the symptoms could be attributed to slow poisoning from this source. Proceeding upon this assumption, methylene blue—which had often been used effectively in this type of poisoning, was suggested as a treatment. One of the physicians used it and reported miracu-

lous results with clearing of cyanosis and signs of toxicity in less than 10 minutes. This affords a therapeutic test which supports the rest of the work.

MEASURES TAKEN TO STOP THE EPIDEMIC

1. The hospital autoclaved all milk until a safe milk supply could be obtained.

2. Whenever possible, stool cultures were made on mothers 2 weeks before they entered the hospital. Upon entry, another stool culture was made and the mothers were questioned concerning a history of diarrhea.

3. Whenever a positive stool culture was obtained, or the mother had a history of diarrhea within the past 2 weeks, or developed diarrhea on the obstetric floor, the mother was isolated on a separate floor, and the infant was taken from the nursery and also isolated from the mother. If a history of diarrhea or a positive stool culture was obtained before entrance, the mother was delivered in her own room.

4. When an infant developed the first suspicious sign of diarrhea, the mother and infant were isolated as above, and the physician notified so that treatment might be started on the infant.

5. Another room was set up for a nursery and all new infants placed in this room until all the infants in the original nursery had been discharged and the nursery could be thoroughly cleaned.

6. All mothers and infants were sent home on the fourth day routinely. The public health nurse was notified when the mother and infant were dismissed from the hospital so that a visit could be made to give the mother instructions on the care of the baby and techniques which should be used to prevent infection. If, on the fourth day, the infant showed signs of diarrhea, he was sent to pediatrics rather than home. If, for some reason, the mother or infant had to stay in the hospital more than 4 days, the mother and infant were placed in a private room and the infant kept out of the nursery.

7. Public health nurses were assigned to assist mothers leaving the hospital with new-born infants, to put into practice every precaution to safeguard infants from infection.

8. Stool cultures were repeated on all nurses in the nursery, and pending report, all nurses who had had diarrhea in the last month were removed from the nursery.

The epidemic subsided within 3 weeks after these measures had been put into effect.

SUMMARY

1. This is a report of an epidemic of diarrhea in 24 new-born in which there were 9 deaths. Eighteen of these probably contracted the disease in the new-born nursery. One was discharged, returning to the hospital as a feeding problem, and developed diarrhea 7 days later. Five developed diarrhea at home after being in contact with a case in the family.

2. The infecting organism was *Pseudomonas aeruginosa* which gained entrance to the milk supply through water which was dripping off of a rag into the pasteurized milk in one dairy. Bottles of dairies were exchanged without proper cleaning and sterilization, so that the organisms easily gained access to the other dairies.

3. The contaminated milk caused an epidemic of gastroenteritis in Great Bend and caused outbreaks among patients and employees of the hospital and in consumers of the Great Bend milk in outlying towns.

4. The infants were secondarily infected by mothers and nurses who drank the milk in the hospital, or by other members of the family after the infants had been dismissed from the hospital.

5. Apparently well persons who had ingested the contaminated milk acted as temporary carriers.

6. Of 24 infants studied clinically, it was possible to study 9 bacteriologically. *Pseudomonas aeruginosa* was isolated in the stools of all 9. Autopsy material was obtained from 2 cases for bacteriological study and *Pseudomonas aeruginosa* was isolated from both.

7. Epidemiological, milk sanitation, and bacteriological studies, all support this conclusion which is further supported by the therapeutic results of methylene blue.

8. The epidemic subsided within 3 weeks after control measures based upon the findings were put into effect.

THE FORGOTTEN MIND

IT is an accepted truism that the health problems related to mental and emotional maladjustment are approximately equal in volume to all the other health problems which confront us. We know that the number of hospital beds occupied by advanced cases of mental and nervous disease nearly equals the number assigned to all other diseases and defects. We know that the burden placed on the average family by emotional maladjustments—fears, inhibitions, suspicions, insecurities, defense reactions of various sorts—are probably as heavy as those due to all types of so-called “physical” diseases in the home. We give lip service to these facts; but what do we do about them? How much serious thought have you, Dr. Health Officer, who read this editorial, really given to the problem in your community? Are you its Health Officer, or only its Physical Health Officer? Can you shrug your shoulders and leave the problem to the psychiatrists? How vital in your thinking, Miss Public Health Nurse, are the problems of mental hygiene which arise in your daily practice? What has the American Public Health Association contributed to this cause? How far does the attention devoted by this *Journal* to the subject of Mental Hygiene, reflect the real importance of the subject and how far is it bound by the inertia of past routine practice in the field of public health?

The U. S. Public Health Service and a few state health departments have stepped out and assumed real leadership; but most of us have failed to act on the assumption that this is really a basic and fundamental responsibility of our profession.

The passage on July 3, 1946, of the National Mental Health Act brings the issue clearly home to us. This law, it will be recalled, provides for erection and equipment of a research institute to be operated by the U. S. Public Health Service as a center for experimentation and specialization in this important field and for grants to outside research centers for the same purpose; for training of essential personnel in the mental hygiene field; and grants to aid in the establishment of mental health clinics for discovery, diagnosis, and treatment of persons with psychiatric disorders. The 80th Congress has provided an appropriation of approximately three millions for the first steps in carrying out the purposes of this Act.

If you feel that this matter does not concern you as public health workers, and as citizens, we recommend a serious perusal of the *Annual Report of the National Committee for Mental Hygiene* for 1946.¹

Let us begin with the problem of institutional care, since historically this has always been our first community avenue of approach. The National Committee points out that about 1,000,000 persons in the United States are sufficiently disabled by mental illness to warrant hospitalization, but that only half that number receive such care. And what is the character of the care which the fortunate half million actually enjoy? Here are some pertinent points brought out by the National Committee in regard to state mental hospitals:

- "(a) Some of our states spend as little as forty cents a day, all told, per patient;
- (b) some state hospitals spend on food only seventeen cents a day per patient;
- (c) many state mental hospitals are crowded to almost twice their capacity;
- (d) mentally ill persons are often housed in buildings long since condemned because there is no money available for new structures."

Is it any wonder that the standards of the staffs of such hospitals tend to reflect the deplorable picture of neglect and mismanagement which these statements reveal? There are twenty times as many unfilled medical posts in our state hospitals as there are physicians willing to take such posts.

That conditions are not far different across our northern border is indicated by a recent article² which points out that in Canada, public mental hospitals are expected to provide board, lodging, clothing, and medical and nursing care for a budget of about one dollar per capita.

Now as to facilities for the outpatient service provided for child guidance and for the treatment of the adult who does not yet need institutional care. This is the most fundamental and most constructive part of our mental hygiene machinery. By clinic treatment, a certain proportion of cases otherwise headed for institutional care will be kept out of the state hospitals; but—what is much more important—thousands of persons are restored to happiness and efficiency who would never, perhaps, be sent to an institution but who would drag out their lives in wretchedness as a burden on family and community.

On this point the National Committee reports that there are 25 states in which not even one child guidance clinic is in existence; and that in the entire country there are less than 400 such clinics. The *Report* notes that only 50,000 boys and girls could get assistance from child guidance clinics in 1946, while over 250,000 teen-agers passed through our juvenile courts. The National Committee estimates the real need of the United States as 1,400 clinics; and points out that "if each outpatient clinic prevented the commitment either of one veteran with a service-connected disability or five civilians a year, more than the estimated cost of operating a clinic (\$32,000 per year) would be saved."

Since Clifford Beers published *A Mind That Found Itself*, in 1908, we have made notable progress in our thinking about the problems of mental health; but our accomplishments in the field of concrete achievement are not much to boast about as the result of four decades. If the public health profession were really to put its shoulder to the wheel, thought might more rapidly be translated into action.

PROGRESS IN THE USE OF FLUORINE FOR THE CONTROL OF DENTAL CARIES

WE have reviewed in an earlier editorial¹ some of the basic evidence presented by Bibby, Dean, and others in regard to the use of fluorine for the reduction of dental caries. More recent findings—along two different lines—warrant a discussion of the progress made during the past three years.

The simplest and most comprehensive method of applying this preventive is the addition of minute amounts of sodium fluoride (one p.p.m.) to a public water supply. One report on this subject has come from Connecticut. Erlenbach and Tracy² compared 187 children in an institution where fluorine was added to the water supply with 149 children in another institution used as a control. After a one year experimental period, the "caries attack rate" was 3.0 per cent and 4.3 per cent in the respective groups, a 30 per cent lower incidence of new carious teeth in the group receiving fluorine. The children in the fluorine series were older, however, on the average and had a high incidence of caries at the outset of the experiment. The difference in new carious teeth may well have been due merely to the fact that the experimental group had already progressed farther along the road of the normal development of caries with age, or as a result of some other physiological variable between the groups.

This is a most important point. Klein,³ in a study of children of Japanese ancestry, reported that at ages between 8 and 10, a group of children supplied with fluorinated water showed (in 2 years) 13 per cent of new decayed or filled teeth against 31 per cent for a control group; while for children between 11 and 14 years, the respective ratios were 11 per cent and 15 per cent. It seems probable that the effect of fluorinated water is most significant in early years. We must await the results of extensive studies now under way at Grand Rapids, Mich., and Newburgh, N. Y., for a more complete answer to this question.

A second method of applying fluorine is that of "topical application." This consists in giving the teeth a thorough prophylaxis, isolating the teeth to be treated by cotton rolls, drying the teeth thoroughly, painting their dried surfaces with 2 per cent sodium fluoride, and allowing the painted surfaces to dry. A carefully controlled series of experiments with this procedure has been reported by Knutson and Armstrong,⁴ in which age and physiological variables were ingeniously controlled by treating only teeth in one upper and one lower quadrant of the mouth. The treatments were applied in 7 to 15 topical applications (to those quadrants) during a period of 8 weeks in the spring of 1942—and 242 subjects have been under observation for 3 years. Results in the upper and lower quadrants were quite consistent and the following general results were obtained for the treated quadrants.

<i>Year</i>	<i>Per cent Less Newly Carious Teeth</i>	<i>Per cent Less Newly Carious Surfaces of Previously Carious Teeth</i>
1942-1943	40	12
1943-1944	47	25
1944-1945	22	33

Whether the decreased improvement in newly carious teeth and the increased improvement in new areas on previously carious teeth is significant is uncertain. With the passage of time, the number of non-carious teeth available to become carious must, of course, decrease. In general, however, the results are encouraging.

It appears that thorough and repeated topical application of fluorine reduces the development of caries by 30-40 per cent; and that the influence of this treatment persists for at least 3 years.

Jordan and Knutson and their associates⁵ have recently reported detailed studies of the effect of varying the number of topical applications and of omitting prophylactic treatment prior to application. The per cent reduction in caries incidence recorded was as follows:

	Treatments				
	1	2	3	4	6
Jordan, with prophylaxis	5	10	21
Knutson, without prophylaxis	..	9	..	20	21

Knutson concludes that the preliminary prophylaxis should be an essential part of the procedure.

Fulton and Tracy have suggested that it might be preferable to make the topical application once every 6 months instead of 7 to 15 times within a short period as was the practice of Knutson. They report a one year experiment on this procedure and compare the results with those of Knutson's first year for two selected age periods, with respect to reduction in caries incidence:

	Age	
Knutson	7-10	47
Fulton	5-10	52
Knutson	11-15	60
Fulton	11-14	53

The question as to the number and spacing of topical applications must be determined by further studies. It seems reasonably clear, however, that topical application is a highly effective procedure; that it should be preceded by a thorough prophylaxis; and that—whatever may be the case with the consumption of fluorinated water—this process is effective with older children.

There is still a third method of applying fluorine, intermediate between its addition to drinking water and its intensive topical application. This is the use of a fluoride mouth wash as a part of the daily tooth toilet. Individuals have claimed highly satisfactory results from this procedure in their families, but we know of no statistical study which has scientific validity in this field. It is still uncertain whether fluorine in a water supply exerts its influence directly on the teeth or through absorption and circulation of the salt to the teeth indirectly. If the latter process is involved it would explain the fact that major effects in this case are produced on the young child. On the other hand, topical application must apparently operate directly on the tooth through its surfaces and this is in accord with its efficacy in older children. It is not easy to see how the use of a mouth wash could produce results anything like as efficient as topical application; and the latter would seem to be, at present, the method of choice. We trust that the dental profession will work out the best procedure as promptly as possible; and we recommend to health administrators and health educators consideration of the inclusion of this procedure in their programs.

It should be noted that the Divisions of Dental Health of Massachusetts and Connecticut and other states are strongly advocating topical application of fluorides. "On March 15, 1947, the American Dental Association published a report in the *American Dental Association Journal* stating, 'The demonstrated relation between the presence of fluorides in domestic water supplies and the

prevalence of dental caries in children has led directly to experimental studies on the effect of the topical applications of various fluorides to teeth. These studies, although not uniform in methods of findings have demonstrated the effectiveness of topically applied fluoride solutions in reducing the incidence of dental caries in children under certain conditions. Considerable research still remains to be done in determining the optimum frequency and method of such applications, but the use of topically applied fluorides by the dentist can now be recommended as a general preventive measure.'"

The number of dentists, even in the United States, is about half the number necessary to care for the present incidence of dental decay, and the ratio of dentists to population has remained between 50 and 60 per 100,000 population since 1920; there were 25 per cent less dental graduates between 1930 and 1940 than in the previous decade. Only a reduction of some 40 per cent in incidence of dental caries could bring this situation into balance; and such a reduction seems a possibility if topical application of fluorine becomes general. The treatment could be organized under public health dentists so that dental hygienists in a clinic would provide treatments at a minimal cost. This may well become an important factor in the public health program of the future.

MYSTERIES OF MEAT INSPECTION

DID you know that you can determine whether a lobster was dead when it was boiled by bending its tail back straight and seeing whether it snaps back into place or not? At what point of said lobster's anatomy should you sniff to determine whether his tissues have become decomposed?

Did you know that you should examine the side of a mackerel, the backbone of a halibut, the eyes of a cod, to determine its degree of mortuary decomposition?

Did you realize that pressure due to forcing meat through a chopping machine too fast, or the chopping of pieces that were too large, or the piling up of meat on a counter during trimming, could produce appreciable increases in temperature, favorable to decomposition? Would you have imagined that a tactful campaign of education could reduce the average bacterial content of chopped meats in a city from 10 million to 200,000 per gram?

The Editor did not know any of these things until he talked recently with the Inspector of Meat and Provisions in a New England city.¹ He came away from the conference with a new reverence for the occult arts of the meat inspector.

Clearing House on Public Health Salary Information

THE following caution is suggested for readers: in any recommendations for salaries for various public health personnel made by the Executive Board of the Association or by its Sections or committees, or by other agencies such as the public health nursing salaries recommended by the National Organization for Public Health Nursing in the June Clearing House, it is understood that, because of the cost of living or prevailing salary levels in other professions in any particular community, the recommended salaries may not be high enough. It is a truism that no single average or median figure of any kind will be applicable to the entire United States.

INCREASED SALARIES FOR ENTERING POSITIONS IN NEW YORK STATE

One of the early announcements to come out of the New York State Health Department following the appointment of the new Health Commissioner, Herman E. Hilleboe, M.D., was of higher salaries to physicians qualifying for the entering position of either Assistant District Health Officer or Senior Public Health Physician.

In announcing these increases, Dr. Hilleboe said:

"We fully realize that even with the recent increases in the salary scale, the pay the department can offer well trained physicians is still not as much as we would like and considerably less than such physicians can make in private practice, but it should attract those physicians who are more interested in helping to prevent unnecessary human suffering than in treating illness which has occurred. The increases granted

will partially compensate these physicians for the increased cost of living, and help to meet the competition of local and federal agencies, such as the Veterans' Administration."

WHAT KIND OF EMPLOYERS ARE WE?

The June *Bulletin* of the National Tuberculosis Association in "What Kind of Employers Are We?" by Edward Funkhouser, raises some questions that might well be pondered as a part of the salary problem, which is after all one aspect of the larger problem, that of securing and holding personnel. The questions raised are:

1. Is there a fair salary policy—fair both in relation to other employees of the agency and to going rates for community jobs of comparable responsibility?

2. Is fair personal treatment for the individual assured through a clear statement of policy as to salary, working conditions, vacations and sick leave, as well as a method of dealing with grievances?

3. Are opportunities for advancement provided and are employees aware of these opportunities and encouraged to prepare themselves to meet them?

4. What are working conditions? Mr. Funkhouser points out, for example, that among tuberculosis associations there is a wide gap between the number of employees enrolled in a retirement plan and the total number of workers. He suggests other security routines such as preemployment, physical examinations, and routine check-ups. He also suggests the value of good tools and good supervision.

INDEX NUMBERS OF INCOME AND COST OF LIVING

The Clearing House has received the following figures on the relative rise in the cost of living, in the incomes of private physicians, public health physicians, and nurses and in the wages of

workers in manufacturing industries, with the notation that they are of interest to the current discussion.

We agree that they are interesting and that they advance our thesis that public health salaries are too low. We wish to point out, however, qualifications that should be borne in mind in drawing conclusions from them.

In the first place, the nature of index numbers must be remembered—that they are not absolute and cannot be related absolutely to each other. They rather represent the distance that each factor has traveled from its respective base line. They do not mean that wages of workers in manufacturing industries are higher than public health salaries; they mean only that manufacturing wages increased faster than public health salaries.

A second factor that must be remembered is that not all starting dates are the same. The later date for salaries of public health physicians is a year

earlier than in the other categories. In that year, the general level of salaries of public health physicians undoubtedly increased, thus raising the index that is comparable with the other groups to a figure beyond 127.

LOCAL AND STATE HEALTH PROGRAMS CURTAILED BY REDUCED APPROPRIATIONS IN WASHINGTON STATE

The following article from Washington State's *Health Commentator* for May, 1947, suggests the presence of still another threat to the current campaign to get public health salaries on a level that will attract well qualified persons. Perhaps another area of education needs to make clear the distinction between real and "Taberized" economy.

"Local health departments throughout the state, faced with a 50 per cent cut in state subsidy funds, are either seeking additional money locally or have

trimmed their staffs and are putting away plans for bettering health services.

"The funds available for state aid to local departments were slashed from \$264,226.50 for the 1945-1947 biennium to \$125,000 for the 1947-1949 biennium.

"Elimination of this aid has made it necessary for 49 positions to be either dropped from the payrolls or paid for by local sources. Some of these positions are unfilled vacancies on the staffs, due to the shortage of trained health workers; others represent trained public health workers who have been released from their jobs.

"The 49 vacated positions include 32 public health nurses, 6 clerks, 7 sanitarians, 2 bacteriologists, 1 health educator, and 1 dental hygienist.

"In addition to personnel cuts, plans for improving local health services, such as developing full-time departments in place of inadequate part-time units, are being shelved. Only 22 counties are now receiving full-time health services, and plans for full-time departments in Whatcom and Grays Harbor counties are being postponed unless money can be raised locally.

"Salary funds for the State Health Department were cut from \$675,358 to \$564,000, although the requested budget was more than twice this amount. This cut necessitated dropping 22 positions from the state staff, as well as tabling plans for expansion in many important fields such as mental hygiene, sanitation, health education, and industrial hygiene.

"The State Health Department's operations budget was increased \$38,270, but this was largely consumed by an increase of \$36,275 in Smith Tower rent rates. Allowing for increased costs of materials and supplies, substantial cuts will also be required in this field.

"Positions dropped from the state staff include 3 physicians, 10 clerical workers, 2 consultant nurses, 1 health educator,

2 statistical workers, 1 venereal disease investigator, and 2 sanitarians. All employees of the department are hired under rigid State Merit System specifications, and personnel practices are entirely removed from partisan politics.

"Services for crippled children also are being curtailed, as the appropriations for this work were reduced from \$239,495 to \$180,400 for the next two years. Due to increased costs of hospitalization and the reduced budget, fewer children needing help can be accommodated during the next two years."

WHAT THE READERS SAY

Apropos of the article in Washington's *Health Commentator* are two communications from that state.

Arthur L. Ringle, M.D., State Health Officer writes:

The Washington State Legislature does not appropriate individual salary items for health department workers, but appropriates a lump sum for "salaries and wages." The cost of living bonus passed by the Legislature in 1945 was incorporated in the Compensation Plan as an integral part of the salary ranges. We feel that our salary ranges are inadequate to attract and retain qualified personnel in our health organization. This opinion is substantiated by a rather complete salary survey which was recently made by the Washington State Personnel Board.

Our Merit System Rule does permit us to employ persons with training and experience above the minimum requirements at a rate above the entrance rate. We have been forced to resort to this procedure in attracting experienced personnel, although we feel that such action is not entirely in conformity with the true spirit of a merit system.

Emil E. Palmquist, M.D., Seattle Health Officer writes:

It is with great interest that I have read the editorials appearing in the May and June issues of the *Journal* relative to salaries being paid public health professional personnel. It is most timely to bring this to the attention of public health administrators. I only wish that public officials who hold the purse strings would be more cognizant of the need for raising salaries. I have used some

of the material from your editorials to stimulate local officials into providing better salaries, especially for physicians of the department. The salaries for public health nurses, sanitarians, and public health engineers, are fairly well up but so far I do not have the physicians' salaries in a good position. At present the physicians' salaries in this department, other than my own, are \$6,180 and \$6,300 annually. Transportation is furnished by means of the City providing an automobile for their use in connection with their work.

I am still looking for an Epidemiologist to head the Division of Acute Communicable Disease Control. The salary for the position is now \$6,180 plus transportation. There is a possibility that this position might also carry an appointment in the new University of Washington Medical School. I am asking the City Council to establish a salary range for these physician-division directors of \$7,200, \$7,800 and \$8,400. They must have specialized training in public health plus training in their particular specialty. The other three positions of this rank are now filled by well qualified public health men, namely, Director, Division of Maternal and Child Health Services, Director, Division of Venereal Disease Control, and Director, Division of Tuberculosis Control.

I am wondering if you can give me any assistance in finding a qualified Epidemiologist. I would prefer to have a younger man who has one year of postgraduate training in public health with specialization in communicable disease control or epidemiology. Experience is desirable but not required.

From about the middle of December until the middle of May, I had an Epidemiologist of good training and qualifications lined up to take the vacant position. He was still in the Army and I expected his release momentarily. About the time his release was due, he accepted another position at an annual salary of \$8,100 in the Civil Aeronautics Administration. This was quite a shock to me since I had been counting on him to come for the \$6,180 annual salary. I have related this experience to the officials in charge of the purse strings locally, but will not know for another two or three months whether I have made sufficient impression to get any substantial increases for next year. To say the least, I am somewhat discouraged about salaries for physicians in public health, and the prospects for the future do not seem to be too good.

You might be interested to know that Dr. John Fouts, the King County Health Officer, resigned effective July 1, 1947. We are now

attempting to effect a consolidation of the City and County Health Departments for this community; namely, the City of Seattle and King County. I do not know yet what the outcome will be but the idea has the blessing of the Medical Society and also of the Seattle Municipal League. I shall let you know when I have any definite information.

EDITOR'S NOTE: The last paragraph is included here advisedly to remind readers that city-county consolidations are closely related to the salary and personnel shortage situations.

V. L. Ellicott, M.D., County Health Officer of Montgomery County, Maryland, writes as follows:

The Health Department of Montgomery County, Maryland, now employs twenty public health nurses. On July 1, 1947, the following salary scale went into effect:

Junior Public Health Nurse (11 positions)	\$2,400
Senior Public Health Nurse (3 positions)	\$2,600
Assistant Supervising Nurse (2 positions)	\$2,800
Supervising Nurse (3 positions)	\$3,200
Director (1 position)	\$3,600

All positions carry three increments of 5 per cent each, which are given at 6, 18, and 30 months respectively, after appointment.

The position of Junior Public Health Nurse does not require university study. The position of Senior Public Health Nurse requires at least 14 and preferably 28 credits (one year of Public Health Nursing). Several of the supervising positions carry administrative responsibilities beyond those of nursing supervision. This accounts for the relatively high ratio of supervisors to staff nurses.

The new salary scale represents an increase of approximately \$500 over the old scale. The principal reasons for the increases were:

(a) Higher salaries are being paid to public health nurses by other agencies in the metropolitan area of Washington.

(b) The former salaries were little higher than clerical salaries and therefore offered little inducement to high school graduates to spend three years in training.

(c) Teachers' salaries have been markedly increased. Nurses' salaries should be approximately equal to those of teachers because the period of training is approximately the same.

The Civil Service status of public health nurses has been changed from subprofessional to professional.

J. Lynn Mahaffey, M.D., Director, New Jersey State Department of Health, writes:

The salaries paid to employees of this department are in accordance with ranges established by the State Civil Service Commission. A system of yearly increments is in force. The compensation plan at present applying was established in December, 1944.

Physicians: A well qualified and experienced industrial physician in the Division of Adult and Industrial Health left the employ of this Division because of inadequate salary. He was receiving \$4,500 per annum and was offered \$7,500 in the same field with a large insurance carrier.

Nurses: The Chief of the Department's Division of Maternal and Child Health reports increasing difficulty in the past several months in securing nurses to fill positions in the field of maternal and child health. The salary established for the position of Public Health Nurse in this state is \$1,800 per annum. While nurses have accepted positions at this salary, they soon leave. At least four have left to take full-time school positions starting at \$3,100 a year; several have accepted institutional positions at \$2,400 a year. Two nurses are considering positions in other states; one was offered \$2,850 and the other \$3,000. In other instances nurses interested and about to accept a position with the division, refuse to work for the \$1,800 salary as they can receive better income in institutional, industrial, or other branches of nursing.

Engineers and other employees of the Bureau of Engineering and Sanitation: Resignations among engineering personnel in recent months number four: three started at \$1,800 with a range up to \$2,280 as hydrobiologist or watershed inspector in 1931, 1939, and 1940, respectively. Their rank was changed to assistant sanitary engineer with a salary range of \$2,400 to \$3,000. In 1944 each was raised to the rank of sanitary engineer with a salary ceiling of \$3,600. Each left in 1946 for more lucrative pay. An additional engineer at the same pay left for the same reason after seven years as assistant sanitary engineer at \$1,800 to \$2,280 and two years as sanitary engineer at \$3,000 to \$3,600. A fifth who was certified by Civil Service did not accept the position of sanitary engineer at \$3,000-\$3,600, and a sixth, that of junior sanitary engineer, at \$2,040-\$2,640 because of the low salary range.

Laboratory Personnel: Two Junior Laboratory Technicians have left the Bureau of Bacteriology because of salary limitations, and there is general dissatisfaction with salaries among technical employees in the Bureau.

X-Ray Technicians: The entrance salary of \$1,680 per annum is insufficient to attract competent technical personnel for the Division of Tuberculosis Control. As a result, it is necessary to employ untrained and unqualified persons. After persons are trained, they are offered salaries double the amount paid by the state, and resignation ensues.

Pharmacologist: The Bureau of Food and Drugs recently lost a particularly well qualified pharmacologist because, upon his return from military service, he secured a position with a drug manufacturing firm at an entering salary of \$5,500 per year, as contrasted with the \$3,000 salary in the department. No other satisfactory candidate has been secured because of the low salary.

Veterinarians; Food Inspectors: Two veterinarians employed in milk control work and two food and drug inspectors have also been lost because of insufficient salary.

Health Education Workers: In the original plan of work for the Division of Health Education there was contemplated the employment of a person who would be trained in still photography to take still pictures as needed for exhibits, news releases, lantern slides, and other uses in health education activities. The salary set by the State Civil Service Commission was \$1,800, which none of five well qualified applicants would consider. The individual who finally accepted the position proved unsatisfactory and was dismissed. Another accepted the position; while his service along certain lines was satisfactory, he was not capable of doing good photographic work. He subsequently left for a better paying position.

Multilith operators receive an entering salary in state service of \$1,440, which has proved inadequate for securing and retaining qualified persons.

The administrative and technical staff of the Division of Health Education report offers of positions in other agencies and in commercial organizations at better salaries. It is feared that economic pressure may eventually bring about the loss of these employees.

Credit Lines

NEW HOME FOR LOS ANGELES HEALTH DEPARTMENT

George M. Uhl, M.D., and David Janison, Health Officer and Director of Health Education respectively of the Los Angeles City Health Department, have prepared this story of how citizens of that city were persuaded to vote a \$6,500,000 bond issue to finance construction of new public health facilities:

On May 27, 1947, the voters of Los Angeles approved a \$6,500,000 municipal bond issue to finance the construction of new public health facilities. It was the first time in the city's 156 year history that the health department was granted an adequate and suitably constructed home of its own. From the time of its creation, the health department has been alternately housed—clinics, laboratory, and all—in a succession of outmoded structures no other governmental agency would have. Two address changes in past years were entirely accidental. The first came when the telephone company delivered an ultimatum to the city to provide rainproof offices for the health department or lose its telephone equipment. So the health department was told to close up its umbrellas and cram itself into one of the oldest buildings in the city, which workmen soon after came around to tear down for the new city hall. Again the health department was moved, this time to a ten story bank-and-office building as a "temporary measure." Twenty-one years later, when the voters approved the \$6,500,000 bond issue, the department was still in its "temporary quarters."

The passage of the bond issue marked a turning point in Los Angeles's public health history. How the city administration successfully convinced the bond-shy voters of Los Angeles that the issue was essential, is a story of extremely close coöperation between all the city departments, the press, radio, and civic groups, and of a strenuous effort on the part of city employees themselves.

Decision for a Bond Issue—Much of the post-war planning for expansion of municipal services, including public health, fire and police protection, combustible rubbish incinerators, playgrounds, and sewer improvements, were worked out by the heads of city departments, the City Council, and the Mayor. Altogether, \$55,500,000 was estimated as necessary for the

expansion, and bond issues for the separate items were decided upon.

The Campaign—Six propositions, covering each of the municipal functions to be expanded by bond issues, were placed on the ballot. A citizens' committee was formed to promote all the issues. Each city department urged support of all propositions; but gave special emphasis to its own bond issue. The citizens' committee was late in getting started, primarily because of the difficulty of raising funds. Finally, the committee succeeded in raising enough money to begin placing billboards, radio spot announcements, small newspaper advertisements and news publicity.

Nearly 2 months before the elections, a delegation composed of the Mayor, the Fire Chief, Police Chief, City Engineer, and Health Officer, visited newspaper editors, radio managers, labor organizations, and representatives of the motion picture industry to elicit support. As a result, the newspapers took an active part in the campaign, and the motion picture industry produced a 4 minute trailer which was exhibited in more than 200 movie theaters for 10 days preceding the election. Radio stations devoted a considerable part of their broadcast time to special spot announcements, dramatizations, and eye-witness reports of the city's limitations. Service clubs held special programs. Hundreds of thousands of pieces of literature, none printed at city expense, were distributed. The slogan on all centrally distributed literature and material was, "Vote Yes on Propositions A through G." Although receiving all this extra mention, Proposition G, which was to have financed the expansion of branch city halls, was defeated even in those districts which it was to benefit. Significantly enough, it was the only proposition which had no additional "educational" support and it was the only proposition defeated.

The health department, on the other hand, through the off-hours contribution of its employees and executives, gave its Proposition F all the "educational" support it could muster. It drew up a graphic handbill, with photographs of an old-time Wild West type of structure contrasted with the city's only modern district health center. Citizens were shocked to learn that both structures were serving the same purpose, and that in the Wild West building a nurse had recently fallen through the floor. Posters were drawn up, support by various organizations was enlisted, talks by the dozen were given, and leaflets

were distributed wherever crowds could be found, in front of public buildings and sports stadia. Thousands of personal post cards were mailed to friends by employees. Newspapers were given every "assistance" possible in their coverage of the department's antiquated facilities, including pictures of the health officer and his secretary lighting up the gas fixtures in his office, which were still intact although modified for use of electricity, and crews trapping rats elsewhere in the building. A running supply of stories pointing up the need was prepared and gradually released to the more than 100 newspapers circulating in the city. Still photographs were prepared for inclusion in the movie trailer. In the words of newspapermen and radio executives, the health department "got more than its share" of publicity.

The Results—Bond issues require a two-thirds majority of votes to be passed, so that opponents can defeat them with a 33.3 percent "No" vote. Because enough "educators" could not be mustered, the proponents decided to let Proposition G coast along on its mention in the campaign slogan. On election night, the earliest returns showed "G" trailing, while the public health proposition, together with fire, police, incinerators, playgrounds, and sewers came through comfortably, and continued to do so until all votes were in. The final count on health bonds was 203,112 for, 88,917 against.

Los Angeles, in the not too distant future, will have a new central headquarters and 6 new district offices for its health department. The voters, having seen how handicapped the department was, felt it would be worth \$6,500,000 plus interest for 20 years to modernize its facilities. And when the city itself begins to realize the benefits of this expenditure, it can thank its health department employees, who gave their own time and money to broadcast the need.

WHAT DO WE KNOW ABOUT REHABILITATION?

The field of rehabilitation and services to the handicapped assumed increasing importance in the period between the two world wars. New governmental and voluntary agencies concerned with rehabilitation sprang up and many already existing health and welfare agencies included rehabilitation activities in their programs. This trend has been greatly accelerated during World War II and the post-war period, due

both to the programs of the armed services and Veterans' Administration and to the effort made by industry to overcome the man power shortage by employing handicapped workers.

Public health workers have become increasingly aware of the importance of rehabilitation in relation to the public health field. Knowledge of the agencies concerned with rehabilitation and services to the handicapped constitutes an essential tool for public health workers; yet the number of health and welfare, educational, and other agencies engaged in some form of rehabilitation activities has made it increasingly difficult to keep well informed.

In appreciation of this difficulty presenting itself to workers in component activities, Dr. Howard Rusk and Eugene J. Taylor have compiled *A Directory of Agencies and Organizations Concerned with Rehabilitation and Services to the Handicapped* (published as a public service by the *New York Times*, price 10¢). The *Directory* lists national organizations and agencies as well as some local agencies. The listings include the name, address, and the name of the executive officer of the organizations as well as a description of the structure, membership, source of funds, program, scope of activities, and publications.

The 133 page booklet will be a valuable addition to health department libraries and many public health workers will wish to keep it on their desks for convenient and frequent reference.

SOCIAL SCIENCE RESEARCH COUNCIL "ITEMS"

With the March, 1947 issue, *Items* of the Social Science Research Council began publication as a quarterly, or oftener if it fills a need. It is intended to be a report of current activities of the Council and grows out of a conviction that there is urgent need for clearer understanding of the role of the social

sciences on the part of the public. Address Social Science Research Council, 270 Park Avenue, New York 17, for information about subscription rates.

HISTORY OF TUBERCULOSIS CONTINUED

The American Sanatorium Association: A Brief Historical Sketch is the third in the historical series by which the National Tuberculosis Association hopes to get into a permanent record the story of the men and movements by which tuberculosis has been brought under control. Written by Lewis J. Moorman, M.D., who has been Director of the Oklahoma Cottage Sanatorium since 1914, and was President of the National Tuberculosis Association in 1933-34, it is the story of Dr. Trudeau and the forces he set in motion which have led to present-day tuberculosis sanatorium practices. Available from state and local tuberculosis associations at \$1 a copy.

RECONSTRUCTION TOWARD EUROPEAN HEALTH

While the brass hats thunder and the power politicians scramble for temporary advantage, various auxiliary organizations of the United Nations go ahead with the fundamental but often undramatic tasks of building a healthy world which alone can serve as a prelude to a peaceful world.

The latest evidence of such a task comes in the notice of an FAO mission to Poland during July and August to survey the country's major agricultural problem, with particular reference to the nutritional level of the population.

The members of the mission are:

Chairman—Noble Clark, Director of the Agricultural Experiment Station, University of Wisconsin

Nutrition and food management—Dr. M. J. L. Dols, Professor of Nutrition, University of Amsterdam

Crop husbandry and marketing—T. J. Harrison, Assistant Commissioner, Canadian Board of Grain Commissioners

Live stock husbandry and marketing—Profes-

sor James Morrison, Queens University, Belfast, and Professor Aksel Milthers, Royal Veterinary and Agricultural College, Denmark

Marketing and preservation of perishable products—Paul Findler, U. S. Department of Agriculture

Preservation of trees—E. N. Munns, U. S. Forest Service

Agricultural economist—Dr. Mordecai Ezekiel, Head of the Agricultural-Industrial Branch of the FAO Marketing and Economics Division

Secretary and rapporteur—Dr. A. B. Lewis, FAO Agriculture Division

THE CASE FOR A FEDERAL DEPARTMENT OF HEALTH, EDUCATION AND SECURITY

Late in 1946, the American Council on Education and the National Social Welfare Assembly jointly sponsored a Committee to study the question as to whether an executive Department of Health, Education and Security, with a cabinet officer at its head, was in the public interest, and to determine what basic principles should be incorporated if such a department were desirable.

The report of this committee was recently published. It gives an excellent summary of the arguments for and against the creation of such a department and outlines the basic principles of legislation creating it. This report should be very useful as background for decisions as to whether to support such legislation in the next session of Congress.

Address, National Social Welfare Association, 1790 Broadway, New York 19.

PUBLIC WELFARE'S STAKE IN REORGANIZING LOCAL GOVERNMENT

Public Welfare, the monthly journal of the American Public Welfare Association, in June, 1947, published an article, "Health and Welfare's Common Concern with the Multiplicity of Local Government." Written by Martha Luginbuhl, Research Assistant of the APHA's Subcommittee on Local Health

Units, this points out that effective administration of public welfare, no less than of public health, requires a broader base than the town or village. *Public Welfare* is to be congratulated on recognizing the urgency of this problem and on giving space to a discussion of the county or the multi-county district as a unit of health and welfare administration.

"BETTER HEALTH" MAKES ITS DEBUT

In December, the North Carolina Social Hygiene Society which had just been chartered under state law, began the publication of *Better Health*, an ambitious bi-monthly journal. It is a part of "the current popular and official movement for the building of hospitals and health centers in the state," which is also reflected in the Good Health Association and the Commission on Medical Care of the state. Nor is this movement confined to professionals—Kay Kyser has lent his name and his talents to make North Carolina health conscious.

MINNESOTA DISCUSSES LOCAL PUBLIC HEALTH SERVICES

The University of Minnesota Center for Continuation Study recently held a two day Continuation Course in Community Activities for Public Health Services.

There were three main panel discussions; one each on the importance of local health services, how to keep our public health nursing programs going, and how we can improve school health. On the panel for the first mentioned were a local health officer, a state district engineer, a county nurse, a local health educator, a representative each of the Minnesota Council of Social Agencies and the Minnesota State Medical Association, and the Secretary of the State Committee on Local Health Services.

This is an interesting illustration of

the several interests that must be brought together in developing community planning for local health services.

SEEING AN OVERWORKED HEART, IN ACTION

The Chicago Heart Association combined health education and a plea for funds in a unique demonstration at a recent luncheon meeting with 85 business executives in the Chicago area. Four hearts were displayed in a bottle: one a normal heart; one a heart about twice normal size belonging to a newspaper executive who had a stroke while arguing with an assistant; a third of a department store executive who would not follow doctor's orders to slow down, and whose distorted heart was puffed like a toy balloon; and the last of a man who had had a heart attack at 65, followed his doctor's orders to relax and died in his sleep at 80.

Louis N. Katz, M.D., Director of cardio-vascular research at Michael Reese Hospital, in presenting the demonstration, declared that one out of every two of the nation's professional men and executives die of high blood pressure or hardening of the arteries. The President of the Association, G. K. Fenn, M.D., asked for \$100,000 for research, saying, "It's a doctor bill, submitted in advance for the doctor bills that would be much larger and that we hope you never will have to pay."

MIGRANT LABOR

The Federal Interagency Committee on Migrant Labor, established in 1946, under authority of the Federal War Mobilization and Reconversion Act, has just made its report which it calls *Migrant Labor—a Human Problem*. It reports varying estimates of from one to five million agricultural and industrial migrants. These "forgotten people of 1947" are "unorganized, unprotected by workmen's compensation laws, ineligible for educational, health, or

welfare benefits . . . and frequently find maintenance of even a minimum standard of living an impossibility." But they are, nevertheless, basic to the nation's agricultural economy.

The committee makes a series of recommendations. Among them are safe transportation ("occupational accident and death rates are probably the highest for any major industry"), establishment of minimum wages, extension of workmen's compensation laws to migrant workers, compulsory school attendance for children, regulation of private employment agencies, and continuance and extension, as required, of the federally sponsored labor camps that have been a part of the national scene for a decade and that will be remembered as the grateful haven of the long-suffering Joads. It is a report that stresses human values but its 9 appendices are a thorough documentation as well. Available from the U. S. Department of Labor, Washington, D. C.

THE FIRST FIVE YEARS OF THE NUTRITION FOUNDATION

The Nutrition Foundation recently issued a report of the first five years of its work. Wholly supported by the food industry, it has appropriated more than a million and a half dollars in the five years. Sixty per cent of this sum was for basic research studies. Research grants have been made to 54 colleges, universities, and research institutes in the United States and Canada and have covered wide areas of nutrition problems. Nine per cent of appropriations were made for education and professional training.

The full report, *Research and the Science of Nutrition*, is available from the Nutrition Foundation, Chrysler Building, New York 17.

SEEING THE SIGHTLESS

The visual arts are heavily drawn upon in the 41st annual report of the

New York Association for the Blind called, *Their Future Is in Your Hands*. Not only is it an annual financial and activity report of this million dollar operation but even more it is a plea for treating the blind like human beings. The Department of Public Relations, which prepared the report, also develops exhibits, radio programs, news interviews to help the sighted in understanding the blind. It also manages the Lighthouse Players, a group of talented blind actresses whose public performances convince audiences that blindness is no deterrent to high adventure and courageous living. The Director of the Association, Philip S. Platt, Ph.D., and the Director of Public Relations, Louise S. Kintner, are to be congratulated on the report—its excellent pictography, photography, typography, and paper and the humanity of its approach.

"HEALTH RESOURCES" APPEARS

Volume 1, Number 1 (February, 1947) of *Health Resources* has arrived from the Marion County (Salem, Ore.) Department of Health. Due to the shortage of mimeograph paper, it is done on heavy green cover paper. It is a very simple but effective attempt to tell the Marion County public what services are available through its Health Department. It is another illustration of what can be done with simple tools and a little imagination and ingenuity.

ANTHRACITE DUST PROBLEM STUDY PUBLISHED

Adequate ventilation and the liberal use of water sprays are the 2 most effective ways to control coal dust hazards in anthracite mines and to protect workers from the respiratory disease known as anthracosilicosis, according to a 3 year wartime survey made by the Bureau of Mines in 38 collieries in the Pennsylvania anthracite region, recently published. The publication was pre-

pared by Leland H. Johnson, Bureau Mining Engineer with the Health and Safety Branch, Wilkes-Barre, Pa. It also covers routine dust sampling and analyzing, use of a wet-type pneumatic drilling machine, removal of dust from roadways, and the use of water in fighting mine fires and removing harmful gases from blasting.

Copies of Technical Paper 704, *Dust Problems in the Mines of the Pennsylvania Anthracite Region*, can be obtained *only* from the Superintendent of Documents, Gov. Ptg. Office, Washington 25, D.C., at 15 cents each.

UNESCO NEWS

On June 15, Vol. 1, No. 1 of *National Commission News* was published. It is the monthly organ of the U. S. National Commission for UNESCO (United Nations Educational and Social Council). It is a useful 8 page pamphlet for keeping informed of one of the United Nation's special commissions. The first issue gives a brief outline of the UNESCO program.

The Director General of UNESCO is Dr. Julian Huxley of the United Kingdom; the American member of the board is Milton Eisenhower, President of Kansas State College, and Chairman of the U. S. National Commission for UNESCO.

National Commission News appears to be available without charge from the Gov. Ptg. Office, Washington, D. C.

REPORTING ON NTA'S MILLION DOLLAR OPERATION

The 40 page 1946-47 *Annual Report of the National Tuberculosis Association* is a condensed story of the wide ranging activities of this 43 year old national organization with affiliated associations in each of the states and territories of the United States.

The year's activities are classified under public health, medicine, and research. The report shows an expansion

into broader fields than tuberculosis. Seven states are now also using seal sale funds for programs on heart disease, social hygiene, cancer control, diphtheria prevention, rheumatic fever, or dental hygiene.

The 1946 seal sale netted more than 17 million dollars of which all but 5 per cent was retained by the state and local associations that raised the amounts. The total income and expenditures of the national association alone were nearly a million dollars.

WORTH ACQUIRING

Nursing Is a Good Profession—In simple language and humorous illustrations this answers such questions as "How do I find out how to become a registered nurse, what do I need by way of education, how do I choose a school, what will it cost, and what are my opportunities after I graduate?" and many others that the high school student or her parents might ask in deciding upon a nurse career. This should be a valuable help in the current nurse recruitment program. Available from Nursing Information Bureau, 1790 Broadway, New York 19, at 5 cents each or \$4 per 100.

Medicine's Fifth Column, by Virgil H. Moon, M.D., Jefferson Medical College Professor of Pathology, has been reprinted from the *Ladies Home Journal*. It is a popular argument against the perennial attempts of antivivisectionists to get state laws passed prohibiting animal experimentation by medical scientists. Available from National Society for Medical Research, 25 E. Washington St., Chicago 2.

A Digest of Nutrition Conferences. This is a report of a series of nutrition conferences conducted by Stuart W. Adler, M.D., Director of the Maternal and Child Health Division of the New Mexico Department of Public Health, and Walter Wilkins, Surgeon (R), U.S.

Public Health Service in 1944. It was first published in 1945 as Vol. 12, No. 2 of the *New Mexico Health Officer* and a supply has now been reprinted. This material, representing an example of postgraduate education, is still of vital interest and is as up-to-date now in concept as when the conferences were held. Available from New Mexico Department of Public Health, Santa Fe, N. M.

Growing Healthfully—Prepared by Mabel Rugen, Professor of Health and Physical Education in the University of Michigan, and published by the National Tuberculosis Association, is a teaching unit for grades I–XII, attractively illustrated and includes a list of suggested publications and their source. Available from your local tuberculosis association.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

The Yale Journal of Biology and Medicine—C.-E. A. Winslow Number—New Haven, Conn.: Yale University, March, 1947, Vol. 19, No. 4. pp. 393-800.

It does not happen frequently that the Managing Editor of this *Journal*, responsible as he is for scanning some forty to fifty books each month and assigning them for review, seizes one with selfish pleasure and reserves it to himself. It almost never happens that the *Journal* reviews a special issue of a periodical. Both these departures from ordinary behavior are occasioned by the C.-E. A. Winslow Number of the *Yale Journal of Biology and Medicine*.

Thirty-nine contributions make up this Festschrift volume for Professor Winslow as he retires as Anna M. R. Lauder Professor of Public Health at Yale University and as Head of the Department. The diverse interests of these contributors reflect the extraordinary versatility of Professor Winslow who is not only a teacher of national and international influence but vitally interested in international health organization, in better administrative practice, in industrial hygiene, in voluntary health agencies, in public housing, in sanitary engineering, in epidemiology, in health education, in school health, in public health nursing, in medical care, in health insurance, in nutrition, in heating, lighting and ventilation, and in making public health a true profession.

As Dr. W. P. Shepard has said, it is not often that within the short span of one man's career he sees the emergence of his chosen field from an aggregation of specialists in various professions to a

profession in its own right. It is still more rare for one man to have had so much to do with that emergence. Professor Winslow has seen public health grow into a profession. No one individual has contributed more to this process of professionalization than he.

Among the contributors are Ira V. Hiscock, Thomas Parran, Sir Wilson Jameson, Philip S. Platt, Leonard Greenburg, John R. Paul, Howard J. Shaughnessy, Ruth Grout, Lucy Morgan, Franklin Foote, Charles Wilson, Martha Eliot, Louis I. Dublin, Leona Baumgartner, Hugh R. Leavell, and the late Courtney Smith. The final chapter represents a bibliography of Professor Winslow, including 574 items in addition to the extensive contributions he has made through such publications as the *New York State Health News*, the *Journal of Bacteriology* (Editor, 1916-1944), and his service as Editor of the *American Journal of Public Health* since April, 1944.

The industry and diligence of the persons who compiled the bibliography must be commended, inasmuch as Professor Winslow himself remarked that many references were turned up which he had entirely forgotten. The one way to have improved it would have been to assign someone to shadow this remarkable man through the years with the sole responsibility of recording for posterity the innumerable gracious and erudite acknowledgments, introductions, and responses made without benefit of manuscript and that are now lost except to those who heard them and remembered. Altogether this is one of the most successful Festschriften that have come to

the reviewer's attention. It is not only well made up and representative of Professor Winslow, but it is a fine volume in itself worthy of a place in every library. REGINALD M. ATWATER

Medicine in the Changing Order. *Report of the New York Academy of Medicine, Committee on Medicine and the Changing Order.* New York: Commonwealth, 1947. 240 pp. Price, \$2.00.

Shortly after it came into being in 1942, the New York Academy of Medicine's "Committee on Medicine and the Changing Order" (Malcolm Goodridge, Chairman) defined its objectives as follows: "To be informed on the nature, quality, and direction of the economic and social changes that are taking place now and that are clearly forecast for the immediate future; to define in particular how these changes are likely to affect medicine in its various aspects; to determine how the best elements in the science of medicine and in its services to the public may be preserved and embodied in whatever new social order may ultimately develop."

The Committee was comprised of some 33 physicians and 17 representatives of allied professions and lay persons. Nursing and dentistry were represented. The lay members were drawn from the ministry, the law, social welfare, the hospital, insurance, labor, and industry. The work of the Committee was given financial support by the Commonwealth Fund, the Milbank Fund, and the Josiah Macy, Sr. Foundation.

The Committee sought information and opinion from a wide variety of authorities. Subcommittees were appointed to organize and study the material thus obtained and to make special investigations of medical education; graduate and postgraduate medical education; the internship; the hospital; administration of public health services; extension of medical services;

the cost of diagnostic and consultant services; industrial medicine; rural medicine; nursing and dentistry. Under the aegis of the Committee some 10 authoritative monographs have been published which contain much of the factual material upon which the Report of the Committee is based.

In this brief review of the Committee's report it is not possible even to list its conclusions and recommendations, much less discuss them. About all that can be done is to point out that the study was planned thoughtfully and skillfully and that it was carried out expertly and with courage and objectivity. It is presented as a judicial, unbiased and constructive study of conditions pertaining to the problems of providing adequate medical care throughout the country. It will be accepted as such by judicious, unbiased readers. It ventilates and illuminates controversial areas of medicine and medical care which are often overheated and poorly lighted. Readers who are genuinely interested in the subject "Medicine and the Changing Order" cannot afford to miss this report. Those whose interest is centered upon preserving the *status quo* will find little in it to encourage them.

HUGH J. MORGAN

Manual for Public Health Nurses—1947–1948. *Minneapolis: Division of Public Health Nursing, Minneapolis: Minnesota State Department of Health.*

This manual covers all areas of public health nursing. It is arranged in two parts, administration and nursing activities. The table of contents with page numbers is an invaluable aid to the reader.

The material is introduced with a discussion of the relationship of the public health nurse to the state and local boards of health and it follows a logical presentation throughout. An admirable feature is the inclusion of per-

tinent records and forms with appropriate topics.

A diagram of the organization of the Minnesota Department of Health includes agencies with which the department coöperates. However, the State Department of Education is not listed.

Wider range of participation in program planning by all agencies concerned with health promotion than was indicated in several sections of the manual is desirable. A loose classification of certain agencies, professional organizations and other groups occasionally appears.

The authors of this manual are to be commended for this generally constructive contribution to public health nursing. Minnesota's public health nurses are fortunate in having this clearly defined and comprehensive manual as a guide in their work.

LULA P. DILWORTH

Penicillin: Its Practical Application—By Sir Alexander Fleming. Philadelphia: Blakiston, 1946. 380 pp. Price, \$7.00.

The volume under review consists of a group of individual articles prepared by British authors, and deals with various phases of the clinical application of penicillin. Only the preface and a short chapter are Fleming's.

The preface reflects the character of the author in that it frankly draws attention to the fact that the clinical reviews are prepared on the basis of information available at the time of writing and that viewpoints will change as experience is accumulated. The volume will probably serve as a chronicle of the status of progress up to the date of publication.

As a reflection of current opinion it probably will not have many adherents. The warning against the indiscriminate use of the antibiotic is timely. Possibly Fleming might have further emphasized the dangers which may accrue from

the promiscuous use of the product in conditions in which the causative organisms are not identified or in which other forms of treatment are known to be effective. Not only is this practice unsound but it may have the effect of reducing the efficacy of penicillin in patients confronted by a lethal emergency caused by pathogens which would have been susceptible under ordinary circumstances.

JOHN F. MAHONEY

Rehabilitation Through Better Nutrition—By Tom D. Spies, M.D. Philadelphia: Saunders, 1947. 94 pp. Price, \$4.00.

This monograph is of timely value to public health physicians, nutritionists, and nurses as well as to private practitioners, medical students, and post-graduates for whom it is specifically planned.

Dr. Spies, a physician noted for outstanding research in nutritional deficiencies, succinctly describes the methods of diagnosis and principles of nutrition therapy which he has found so successful in rehabilitating hundreds of malnourished patients.

Emphasis is placed on the many factors present in nutritive failure and the four essential steps in treatment, including recognition of the time element. Diagnosis of vitamin and protein deficiencies and various anemias is followed by detailed description of therapeutic principles and results. Use of foods, synthetic vitamins and supplementary products is illustrated with four different meal plans.

Excellent photographs of clinical manifestations and simple charts of findings lend clarity and interest.

DOROTHEA E. NICOLL

Public Health Nursing in Syphilis and Gonorrhea—By Evangeline Hall Morris. Philadelphia: Saunders, 1946. 239 pp. 18 illus. Price, \$2.25.

The author states in the preface of her book that it is an "attempt to deal with current problems of the social hygiene program and to include related material which is of special interest." The book accomplishes these aims well and the author has given us a wealth of factual material about the venereal disease program in its broadest scope. The historical sidelights provide interesting background in understanding the many attitudes and misinformation about the diseases.

The chapter on Family Life Education deals with the prevention of the disease and the manifold implications.

The chapters on The Patient and His Needs, and The Work of the Public Health Nurse place emphasis on the need to treat the patient as an individual recognizing his many needs.

The bibliographies at the end of each chapter provide excellent references which will give the nurse more detailed information.

This brief volume provides an excellent reference book for public health nurses as well as all members of the professions. It will be especially valuable to students as a reference book.

HELEN E. WEAVER

Teaching in Schools of Nursing—
By Loretta A. Heidgerken, R.N. Philadelphia: Lippincott, 1946. 478 pp. Price, \$4.00.

This book on principles and methods of teaching by an assistant professor of nursing at the Catholic University of America is well organized, simple, and specific. There are adequate topic outlines, summaries, and index. Extensive, authoritative references are listed at the end of each chapter. Principles set forth are those currently accepted as sound, and the methods proposed are in harmony with these principles.

At a time when nursing is undertaking a study of conditions affecting the quality of nursing education, Miss

Heidgerken calls attention to a crucial and often neglected point in the learning situation—the point where student and teacher meet. "The teacher determines the educational fate of her students by what and how she teaches." This concept of the teacher's part in the development of a good nurse is consistently maintained.

The book should prove useful for teachers and even more specifically for prospective teachers of nurses.

MARGERY T. OVERHOLSER

State-Local Relations—Report of the Committee on State-Local Relations. Chicago: Council of State Governments, 1946. 228 pp. Price, \$3.50.

With the shrinking of the world due to ever faster means of communication and transportation and with the social revolution of the last decade, the interrelationships of federal, state and local governments have of necessity also changed. Recognizing the need for clarifying these relations, the Council of State Governments in 1945 established a Committee on State-Local Relations to study the broad field and to develop a report with definite recommendations.

The present volume is the report of that committee's work. The general summary of the report and the summaries preceding each of the six chapters are excellent. Although the committee's recommendations are nowhere categorical and various alternatives are reasonably presented, the direction of necessary changes is nevertheless obvious.

The recommendations are definitely not in the direction of more centralized state government but rather for greater powers to local units of government. To reach this goal, however, the long run pattern of local government must undergo a fundamental reorganization. Changes in structure must look toward one local government for one local area, for a local government large enough in terms of population to permit effective

public services at low cost and wealth enough to support a substantial portion of those services. It suggests various ways of meeting these goals, the city-county consolidation, for example, in urban areas and consolidation of counties in rural areas. It estimates, for example, that two-thirds of all the counties in the United States have areas of less than 800 square miles which is suggested as a conservative size of convenience; nearly two-thirds of counties and 95 per cent of towns and townships have populations of less than 25,000.

This is a valuable reference work for anyone who must deal with various levels of government and particularly for the state official whose task is to further consolidation of local units. He will also find this bit of useful advice, "The persuasive devices of supervision are the most effective."

MARTHA LUGINBUHL

A Medical Survey of the Bituminous Coal Industry: Report of the Coal Mines Administration—*Washington, D. C.: U. S. Government Printing Office, 1947. 224 pp. XXIV pp. foreword and preface. Supplement, 67 pp. Price, \$1.75.*

The study was made under the direction of Rear Admiral Joel T. Boone, Medical Corps, U. S. Navy, by a staff of naval officers, enlisted men and civilian technical advisers, pursuant to Section 5 of the agreement of May 29, 1946, made by J. A. Krug, then acting as Coal Mines Administrator of the U. S. Government (now Secretary of the U. S. Department of Interior), and the President of the United Mine Workers of America, John L. Lewis.

Under the terms of Section 5, the Coal Mines Administrator agreed to have made, "A comprehensive survey and study of the hospital and medical facilities, medical treatment, sanitary, and housing conditions in the coal mining areas. The purpose of this survey will

be to determine the character and scope of improvements which should be made to provide the mine workers of the nation with medical, housing, and sanitary facilities conforming to recognized American standards."

The bituminous coal industry is big industry. In 1946, more than 525½ million tons of bituminous coal were mined in the United States. The largest part of this was produced in eight of the states, but twelve other states also produced considerable amounts. In the year 1945, more than 383,000 men were employed in 7,033 bituminous coal mines. An index of the economic status of the bituminous coal miner may be obtained from a consideration of a few basic figures. In 1945, the average hourly earnings were \$1.24 but there has always been great variation in the number of hours worked each year in the same mine and among the various mines. The report gives the estimated average annual earning of bituminous coal miners for the year 1945 as \$2,650.

The field work of the study was done by five field teams, each composed of a medical officer, an engineering officer, and a welfare and recreation officer, together with a chief yeoman as clerk. The selection of the mines to be studied was based on a population basis with a random selection of the mines themselves. "In those districts in which the population of miners was largest, the most mines were selected." As a result, 14 per cent of the mines in government custody (260 mines), employing 22 per cent of the miners (71,850), and yielding 18 per cent of the coal output, were studied. In the opinion of the reviewer, this sampling procedure was eminently satisfactory and undoubtedly yielded representative findings.

The body of the report is presented in seven sections, namely, housing and sanitary facilities, public health, industrial medicine, general medical services, hospitalization, hospital facilities, and off-

the-job living. Each of these is in turn broken down into a number of sub-headings in which the material is presented in a summary fashion which is unusually succinct but, nevertheless, so well substantiated factually as to be very convincing. For example, the section on housing presents a discussion of sites, roads, architecture, bathrooms, age of houses, occupancy, maintenance, screening, housekeeping, fire protection, heat and light, leases and sales, bachelor quarters, water supplies, sewage disposal, garbage collection and disposal, and wash houses.

It is quite impossible, in the space of a brief review, to present a detailed discussion of the findings of this large report. Suffice it to say that in general the provisions and facilities were disclosed to range in quality from very bad to good. To cite a simple example, bathrooms were observed in only 10 per cent of company owned houses, while of privately owned houses 31 per cent had bathrooms with tubs or showers or both. Some 11.6 per cent of company owned houses were provided with sewage systems and septic tanks, while 41.7 per cent of privately owned houses were so provided.

It is quite apparent that the coal worker does not share the degree of benefits which one finds other workers of approximately the same economic status enjoying. The report concludes with six pages of recommendations which point up to the important future steps which must be taken to bring the coal mining industry and the workers in the industry to what might be considered the general level surrounding the workers of similar economic status of other industries in the country. The report closes with a supplement, *The Coal Miner and his Family*. This presents a very interesting picture of the life and surroundings of the coal miner, separate from his occupation. The topography and make-up of the report is excellent

and throughout one finds photographs which are at the same time interesting and informative and fine examples of the photographer's art.

The Coal Mines Administrator and the Director of the Medical Survey Group are to be congratulated on the production of a most interesting and valuable public health document.

LEONARD GREENBURG.

Babies Don't Bounce—By Bil Sullivan. New York: McGraw Hill, 1947. 48 pp. Price, \$1.50.

The author of this book of amusing and instructive cartoons in eye catching blue and pink, presents his points with the realism of actual experience. He is the father of Kathy, 4½, and Bil, Jr., 6 months.

Part One deals with Baby vs the Home, and Part Two is entitled, Baby Goes Out.

In forty-one lively sketches as many common hazards are pointed out. As the foreword says: "Keeping an eye on Baby is a twenty-four hour job but it's worth it! Wee One reacts automatically to noise, motion and various original ideas of his own, though not always in the best interests of safe living. Our purpose is to give mother (and Dad too) pointers on how to anticipate the entanglements her offsprings may get into in the course of everyday living."

The public health nurse and pediatrician may find this little text a useful tool in safety education.

E. M. HENDRIKSEN

The Future of Housing — By Charles Abrams. New York: Harper, 1946. 428 pp. Price \$5.00.

The United States has no housing policy or program. Instead we have a serious nation-wide problem and no immediate prospects for its solution. Until more voters know more about the morass of housing, there is unlikely to be legislative enthusiasm to tangle with the

basic issues involved in providing decent shelter for all Americans.

Mr. Abrams's latest book would be interesting even if it was not important. Seldom does an author treat so effectively such fundamental issues as are set forth and discussed in this volume. In each of 5 parts (The Problem, The Real Estate and Construction Enterprises, The Era of Enlightenment, The Housing Agencies, and Toward Solution), the facts are presented clearly, discussed intelligently, and utilized constructively. *The Future of Housing* is likely to evoke indignant bleats from the vested interests in real estate and building construction, if any of them perchance should read it.

Public health personnel who study this volume may be startled and in all likelihood will be stimulated to further their knowledge of and interests in housing. For the health administrator, the chapters on the housing problem, planning, and the aims of a housing program are particularly pertinent.

M. ALLEN POND

Physical Fitness Workbook—
By Thomas Kirk Cureton. (2nd ed.)
St. Louis: Mosby, 1947. 150 pp. Price, \$2.50.

This workbook, designed for college men, describes the plan used at the

University of Illinois for appraising physical fitness and progress made in improving such fitness. Physical fitness is conceived as including: physique, organic efficiency and motor fitness—a concept associated with physical efficiency in an earlier era. Physique is determined by a series of anthropometric measures—girths, skeleton, fat, vital capacity, and muscle tone. Organic efficiency is determined by tests of respiratory fitness (e.g. breath holding), and cardiovascular efficiency (e.g. Schneider Test and adaptations). Motor fitness is determined through an elaborate battery of physical stunts and exercises designed to “measure” flexibility, balance, agility, endurance, and strength. The soundness of this concept of physical fitness may be questioned since little attention is given to the health examination (required *only* before motor fitness tests are given), and the correction of remediable conditions, or to health practices other than exercise. In other words the conditions which must be present before the physiological benefits of exercise are likely to accrue are not considered in this reference. The workbook has greater value, albeit limited, in the improvement of the physical education program in the college than in contributing to the health program. MABEL E. RUGEN

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

ASSOCIATION NEWS

SPEAKERS AT WESTERN BRANCH A.P.H.A. ANNUAL MEETING DECORATED BY HAWAIIAN GROUP

At the meeting of the Western Branch American Public Health Association held in San Francisco, Calif., the Hawaiian delegation brought fresh leis by air from Honolulu for the officers and speakers at the Branch meeting. These were presented at the Banquet Session on May 27.

Left to right: Miss Laura A. Draper; Karl F. Meyer, Ph.D., President, Western Branch; Florence Sabin, M.D., President-Elect, Western Branch; Reginald M. Atwater, M.D., Executive Secretary, A.P.H.A.; Thomas Parran, M.D., Surgeon General, U.S.P.H.S.; and V. Mary Crosse, M.D., Senior Medical Officer from Maternal and Child Welfare, Birmingham, England.

SOUTHERN AND WESTERN BRANCH A.P.H.A. MEETINGS FIXED FOR 1948

The officers of the Southern Branch American Public Health Association of which John M. Whitney, M.D., New Orleans, La., is Secretary-Treasurer, have announced that the 1948 meeting of the Southern Branch will be held in New Orleans beginning April 12 at the Roosevelt Hotel. Particular attention is

called to this date because of the desire to avoid conflicts with other meetings in the territory of the Branch.

The officers of the Western Branch A.P.H.A. of which Walter Mangold of Berkeley, Calif., is Secretary, have announced that the 1948 meeting of the Western Branch will be held in Salt Lake City, Utah, the last week of May. Requests have been received for the organization of a team of speakers to

attend state meetings before and after the dates of the Western Branch.

The Executive Board of the American Public Health Association has expressed itself as eager to serve the Branches and the state public health associations, especially those affiliated with the A.P.H.A., in connection with their annual meetings. It is recognized that much more help can be offered when these meetings are related to the dates of the Branch sessions. The Board has directed that priority should be

given in 1948 to requests which may be received from affiliated societies in the territory of the Southern Branch. In case there should be a desire on the part of these associations to set their dates in a consecutive pattern which would make it possible to utilize a group of speakers selected on a national or perhaps an international basis, the A.P.H.A. office will welcome communications from the officers of Affiliated Societies and other state associations wishing to participate in 1948 plans.

APPLICANTS FOR FELLOWSHIP

In accordance with the By-laws of the Association, the names of applicants for Fellowship are officially published herewith. They have requested affiliation with the Sections indicated. Action by the various Section Councils, the Committee on Eligibility, and the Governing Council will take place during the Atlantic City Annual Meeting.

RESUMES

A 1947 session of the New England Health Institute was held in Durham, N. H., June 16-18 under the auspices of the 5 New England State Departments of Health with the New Hampshire State Department and the University of New Hampshire hosts to more than 800 registrants.

Among the features of the three day meeting was the first joint sectional meeting at which several speakers emphasized the importance of community participation, not only in backing the health officer, but in real coöperative program planning. There was an admirable survey presented of what the Hospital Survey and Construction Act can mean to a local community both from the standpoint of bricks and mortar and from the standpoint of building a coördinated community health program.

Professor Ira V. Hiscock of Yale presented an excellent review of the problem of district health units in New England which involves town and city relationships somewhat different from the rest of the United States. Other features of the program included emphasis on health education, geriatrics, cancer and mental hygiene, as well as on industrial hygiene.

W. Lloyd Aycock, M.D. of Harvard presented a fruitful and suggestive analysis of the broader problems of epidemiology as applied to poliomyelitis.

The last session of the Laboratory Section indicated real progress in the laboratory diagnosis of influenza and in the classification and recognition of the cause of enteric infections.

An unusual list of prominent speakers featured the program and a resolution was unanimously passed urging the United States Congress to approve adherence by the United States to the Constitution of the World Health Organization.

CUBA APPOINTS NEW DIRECTOR GENERAL OF HEALTH

On June 11 Dr. Ramon Grau San Martin, President of the Republic of Cuba, appointed Dr. Luis Espinosa y G. Caceres as Director General of Public Health. Dr. Espinosa has been serving as Director of the Division de Relaciones Medicas y Sanitarias Pan-americanas in the Cuban Government.

DR. SCHEELE TO HEAD NATIONAL CANCER INSTITUTE

At the recent quarterly meeting of the Advisory Council of the National Cancer Institute, the resignation of R. R. Spencer, M.D., as Chief of the Institute was announced, effective July 1. He was succeeded by Leonard A. Scheele, M.D., formerly Assistant Chief of the Institute.

Dr. Spencer will remain with the Institute and in his own words is "shedding the constantly increasing load of administrative duties in order to spend full time on the two phases of the cancer program that interest me most—professional education and research."

At the same meeting, the appointment of Dr. A. C. Ivy, Vice President of the University of Illinois and one of the country's leading physiologists, as Executive Director of the National Cancer Advisory Council was announced.

TYPHUS COMMISSION MEDAL TO
COL. RUDOLPH

Myron P. Rudolph, Colonel, MC, AUS, was awarded the United States of America Typhus Commission Medal recently by the War Department.

The citation notes that he "distinguished himself by exceptionally meritorious service in . . . the work of the Commission, by planning and supervising with marked ability and conspicuous success the administration . . . of details for the control of a typhus fever epidemic raging in the midst of thousands of concentration camp internees . . . He rendered invaluable service by organizing in the Dachau camps and in Southern Bavaria medical units and agencies on a large scale maneuver to bring the typhus epidemic under control."

STOVALL CANCER AWARD ESTABLISHED
IN WISCONSIN

It has been announced in Madison, Wis., by the State Division of the American Cancer Society that an award honoring William D. Stovall, M.D., who is President-Elect of the Wisconsin Medical Society and Director of the State Laboratory of Hygiene, has been established. An annual award of \$250 will be made to a Wisconsin resident student at the University whose primary academic interest is related to cancer. According to the announcement the grant has been created as a tribute to Dr. Stovall for his years of faithful service to the cancer organization and in recognition also of his accomplishments in developing a public consciousness of malignant growths. The first award was made on May 26 to a veteran enrolled in biochemistry, Myrton C. Rand.

NEED A PATENT FREE?

The Office of the Solicitor, U. S. Department of the Interior, has recently advised the Association of certain

patents which have been assigned to the Secretary of the Interior and which are available for licensing. Such licenses are customarily used on a non-exclusive royalty-free basis. The announcement goes on to say that it is the desire of the office of the Solicitor to see the patents as widely used as possible.

From the titles, most of the material listed would not have any application to public health activities. Two titles, however, "Water Survey Apparatus," and "Production of Potable Water from Saline Solutions," indicate some possible application to the field of public health.

Anyone desiring further information should address the Solicitor, Department of the Interior, Washington 25, D. C.

DR. PORTERFIELD APPOINTED OHIO
DIRECTOR OF HEALTH

John D. Porterfield, M.D., M.P.H., has been appointed Director of Health of the State of Ohio by Governor Herbert, effective August 1. Dr. Porterfield, who is a native of Chicago, received his Medical Degree in 1938 from Rush Medical College of the University of Chicago, and his M.P.H. in 1944 from John Hopkins University. He has served for 8 years in the Commissioned Corps of the U. S. Public Health Service, reaching the rank of Surgeon before being released from active duty to accept his present position. During the war he spent 14 months in the Caribbean area, serving as Public Health Service Venereal Disease consultant in the American possessions. He was a consultant, clinic director, and instructor at the School of Tropical Medicine, San Juan, Puerto Rico, and did surveys in International health for the Anglo-American Caribbean Commission, visiting British Guiana, Jamaica, and the British West Indies. For 18 months Dr. Porterfield has been Chief of the Division of Venereal Disease Control in the Ohio Depart-

ment of Health, but since March, 1947, has been attached to the Research Grants Division, National Institute of Health, Bethesda, Md., working in connection with grants-in-aid for medical research. Dr. Porterfield succeeds Roger E. Heering, M.D., M.P.H., who has resigned to enter private practice.

LEGION OF MERIT AWARDED TO DR. LARIMORE

The War Department has announced that the Legion of Merit has been awarded to Captain Granville W. Larimore, M.C., A.U.S., of New York City, presently the Director of Health Education in the American Cancer Society. According to the citation, Dr. Larimore, while serving in various capacities in the preventive medicine service, Office of the Surgeon General, performed notably outstanding service. As Chief of the Education Branch, Venereal Disease Control Division, he was a key figure in promoting a complete Army-wide venereal disease education program. Also as Chief of the Health Education Unit his responsibilities were extended to all health education matters in the field of preventive medicine. Dr. Larimore is a graduate of Rush Medical College, University of Chicago, in 1936. He holds an M.P.H. degree from the Harvard School of Public Health.

MERCK AWARDS FOR TRAINING SCIENTISTS

Late in May, the National Research Council announced 5 awards to provide promising young scientists with further research training in the closely allied fields of chemistry and biology. The research will be carried on in various biochemical subjects at the California Institute of Technology, Rockefeller Institute for Medical Research, the Universities of Wisconsin and Rochester, and the Naples, Italy, Zoological Station.

A. N. Richards, M.D., of the Uni-

versity of Pennsylvania, is Chairman of the Merck Fellowship Board of the National Research Council. Applicants may apply to this Board (2101 Constitution Avenue, Washington, D. C.) for fellowships at any time. The closing date for the academic year 1948-1949, is December 31, 1947.

1947 OCCUPATIONAL DISEASE COMPENSATION LAWS

The Legal Committee of the Industrial Hygiene Foundation, whose Chairman is Theodore C. Waters, has prepared an analysis of the new occupational disease compensation laws enacted in 5 states at the 1947 sessions of their legislatures. It also summarizes the amendment to the New York Occupational Disease Law and reports the appointment of legislative commissions to study such legislation in Vermont and Montana.

This analysis is available, apparently without charge, from the Industrial Hygiene Foundation, 4400 Fifth Avenue, Pittsburgh 13, Pa.

RHEUMATIC HEART DISEASE TO BE STUDIED IN NEW YORK

The New York University College of Medicine in cooperation with the New York City Health Department will study the crippling effects of rheumatic fever and rheumatic heart disease among school children. The study will be made in the Lower East Side District where a preliminary study was made in 1946. Of nearly 1200 eighth grade children examined at that time, more than 3 per cent were found to have existing or potential heart disease. In all of New York City, it is estimated that 7,000 school children have rheumatic fever.

The study will be directed by Elvira DeLee, M.D., of the Department of Preventive Medicine of the New York University. It is supported by the New York Heart Association and the U. S.

Public Health Service, and will have the coöperation of the New York City Department of Education, the New York School of Social Work, the Metropolitan Life Insurance Company, the Rheumatic Fever Council of the American Heart Association, and the U. S. Children's Bureau.

AMERICAN HEART ASSOCIATION ELECTION

At the annual meeting of the American Heart Association in Atlantic City, June 6-7, Dr. Arlie R. Barnes, was elected President and Dr. Tinsley R. Harrison, President-Elect. Other officers are Dr. Carl J. Wiggers, Vice-President, Dr. Harry E. Ungerleider, Secretary, and Samuel Harrell, Treasurer. Thomas I. Parkinson, President of the Equitable Life Assurance Society of the United States, was named Chairman of the Board of Directors.

KANSAS CITY HEALTH DEPARTMENT INTEREST IN PREVENTION OF HOME ACCIDENTS

Harry F. Schulte, Industrial Hygiene Engineer, Kansas City Metropolitan Area Health Department, recently gave a discussion of the toxicity of common solvents used in home dry cleaning and painting, before the Missouri Public Health Association meeting. The department is making a meritorious effort to publicize information of this character which will prevent a type of home accident that occurs frequently.

WHITNEY FOUNDATION TO STUDY RHEUMATIC FEVER

The Helen Hay Whitney Foundation for Rheumatic Fever Research was recently organized. It will stimulate research into the cause of rheumatic fever which is the leading fatal disease of childhood as well as the later cause of crippling heart disease. The Foundation will stimulate research through grants-in-aid to universities, hospitals, and other research institutions. Its first un-

dertaking will be a survey of resources and needs in the rheumatic fever field.

The Medical Director of the newly organized Foundation is T. Duckett Jones, M.D., who is also a director of the American Heart Association and Chairman of its Council on Rheumatic Fever. He is a member of the Advisory Committee on Crippled Children's Services of the Federal Security Agency.

Temporary headquarters of the Foundation are at New York Hospital, 525 East 68th Street, New York, N. Y.

INDUSTRIAL HYGIENE DIVISION IN ARKANSAS

The 1947 Arkansas State Legislature passed the Industrial Health Service Act establishing a Division of Industrial Hygiene in the State Board of Health. The act authorizes the Division to investigate places of employment, and to study the conditions which might be responsible for ill health of the industrial worker. The Board of Health will also adopt rules and regulations pertaining to the control of industrial health hazards.

RETIREMENT OF MARY SWAIN ROUTZAHN

Early in June the Russell Sage Foundation announced the retirement of Mrs. Mary Swain Routzahn who has been Director of the Foundation's Department of Social Work Interpretation. She began her service in the Foundation in the Department of Surveys and Exhibits 35 years ago with her husband, the late Evart G. Routzahn. She pioneered in developing many of the present-day techniques of presenting information to the public. Together also, they with others organized the Public Health Education Section of the American Public Health Association, and developed guides and study courses for students of publicity techniques. Mrs. Routzahn helped to found the National Publicity Council for Health and

Welfare Services and for many years directed its work. In 1944 the first national Elizabeth Severance Prentiss Award in Health Education was made to Mrs. Routzahn, and posthumously to Mr. Routzahn. Mrs. Routzahn will continue teaching courses in social work interpretation at the New School of Social Work, and serve as Consultant to the National Publicity Council.

DEATH OF DR. HILL

Hibbert Winslow Hill, M.D., D.P.H., died on May 23 at the home of his son in Hackensack, Minn. For half a century a public health worker in both Canada and the United States, Dr. Hill was a pioneer in the development of public health as concerned with the individual and not merely with the physical environment. His *New Public Health*, *The New Hygiene*, and *Sanitation for Public Health Nurses* all expressed his deep sense of the obligation of the profession to the public, and his keen critical evaluation of existing public health methods. He was the first bacteriologist to serve in a full-time capacity in Canada and he was the first official epidemiologist in the United States.

Retired since 1934 because of ill health, he had previously been Professor of Bacteriology in the University of British Columbia, Director of the Institute of Public Health in London, Ontario, and Executive Secretary of the Minnesota Public Health Association. Between 1905 and 1912 he was with the Minnesota State Board of Health, first as Assistant Director of Laboratories and Assistant Professor of Bacteriology in the University of Minnesota, and later as Director of the Division of Epidemiology.

BRITISH HEALTH CONGRESS

At the latest Health Congress convened by the Royal Sanitary Institute in Torquay, England, June 2-6, 1947

government departments, local authorities, and scientific bodies were represented. Among the American representatives were Harry S. Mustard, M.D., President of the A.P.H.A., and Martha M. Eliot, M.D., of the U. S. Children's Bureau and President-elect of the Association.

According to *The Medical Officer*, "uncertainty and anxiety about the future under the National Health Service Act was reflected throughout the discussions . . . particularly the problem of the future career of the district M.O.H."

Sir Andrew Davidson, Chief Medical Officer, Department of Health for Scotland, ended his presidential address with "The grim experience of the past few years and the potentialities of modern scientific discoveries for good and for evil alike, bring home urgently and acutely the fact that the destiny of mankind depends upon the benign attributes of the human mind and heart. Few are so favourably placed to guide that destiny as those concerned with the preservation of the health of the world's peoples."

IN-SERVICE TRAINING IN ACTION

"What's New in Public Health," a series of 12 lectures for public health workers in the North Metropolitan District of the Massachusetts Department of Public Health, was held in the spring of 1947.

Realizing that during the war years due to heavy work schedules and other restrictions, it had been difficult for workers to keep pace with the many new developments, Dr. A. Daniel Rubenstein, Health Officer of the North Metropolitan District, planned the lectures. Expenses of the course were assumed by the Middlesex Health Association, and Harvard School of Public Health provided the facilities.

Members of the Harvard School of Public Health faculty, staff of the Massachusetts Department of Public

Health, and national public health experts gave the various lectures. Sixty-seven public health workers including board of health, school, and industrial nurses; board of health agents; and health educators attended the sessions.

"EYE-BANK" FOR BOSTON

The Eye-Bank for Sight Restoration (national headquarters, 210 East 64th Street, New York, N. Y.) celebrated its second anniversary in May by establishing an affiliated eye-bank in Boston, prepared to serve the needs of New England. Seven hospitals in the Boston area and one in Maine have already become affiliated with it. In 1946 the first anniversary was marked by the announcement of an eye-bank in Chicago to serve the Midwestern area.

The parent association and its affiliates collect and preserve healthy corneal tissue from human eyes for transplanting to blind persons who have lost their sight because of corneal defects. The demand for eyes still exceeds the supply. Among the activities of the eye-bank is public education to urge persons to donate their eyes for use after death.

LINCOLN AND LANCASTER COUNTY, NEBRASKA, JOIN FORCES

By authorization of the 1947 Nebraska legislature, the Lincoln City Health Department was recently extended to include all of Lancaster County, thus forming a consolidated city-county unit.

The Health Officer of this city-county unit is Corinne S. Eddy, M.D. She has had previous public health experience in both Alabama and Mississippi.

CHARLESTON AND KANAWHA COUNTY HEALTH DEPARTMENTS MERGE

On July 1, the largest county in West Virginia, Kanawha, consolidated with its chief city, Charleston, which is also the state capital, to form a city-county health unit. The consolidation of the

two agencies had long since been advocated by the U. S. Public Health Service and the State Department of Health, and represents the successful culmination of a drive by many agencies to combine the overlapping city and county health work. The city council of Charleston and the county court have each appropriated \$32,000 for the operating expenses for the new fiscal year. This represents an initial per capiti appropriation of about 33 cents from local funds.

The director of the new city-county unit had not been appointed at the end of July.

TWO NEW BUREAUS CREATED BY WEST VIRGINIA PUBLIC HEALTH COUNCIL

At a recent meeting the West Virginia Public Health Council, upon recommendation of the State Health Commissioner, created a Bureau of Mental Health which is being financed by funds available through the National Mental Health Act recently passed by Congress and matching state funds. W. B. Rossmann, M.D., Charleston, will head the Bureau of Mental Health.

The passage in the 1947 Legislature of a hospital licensing bill led also to the creation of a Bureau of Hospital and Medical Care. Inasmuch as the licensing act becomes effective July 1, 1948, this Bureau will not be put in operation until that time.

INDUSTRIAL HYGIENE IN HIGH SCHOOL

High school students in Portland, Ore., will learn the meaning of industrial hygiene and how it is practiced, especially in Portland industries. The superintendent of schools has announced that the unit will be taught as a part of the health course of study. This is the first time that industrial hygiene has been an integral part of such a high school course.

The lessons are designed to acquaint students with the health hazards they

may meet in future jobs, the physiological effects of the hazards, and the preventive measures which may be employed. Emphasis is placed on the necessary cooperation of the workers to prevent occupational disability.

Authors of the plan are health education specialists, high school health teachers, and members of the Division of Industrial Hygiene, Oregon State

in Chicago, May 19. The Borden award for 1947 was presented to Leonard A. Maynard, Ph.D., Ithaca, N. Y., for contributions to the physiology of milk secretion, factors affecting milk production and milk composition, and the requirements of animals for dietary fats. The Mead Johnson and Company award for research on the vitamin B complex was presented to Dr. William J. Darby, Associate Professor of Biochemistry, Vanderbilt University School of Medicine, Nashville, Tenn., Paul L. Day, D., Professor of Physiologic Chemistry, University of Arkansas School of Medicine, Little Rock, and E. L. Robertstad, Ph.D., Research Chemist, Merle Laboratories, Pearl River, N. Y., for their investigations on B complex vitamins with special reference to studies in the chemistry and nutritional significance of folic acid.

COURSE IN INDUSTRIAL HYGIENE
GEORGIA SCHOOL OF TECHNOLOGY
The division of graduate studies of Georgia School of Technology has just completed an 11 week course in industrial hygiene for engineers. It was designed to provide a comprehensive background for men with collateral scientific or engineering training who are interested in work in industrial hygiene.

The need for personnel in industry as well as governmental work prompted arrangements for this intensive one-quarter course at graduate level.

MARYLAND DIVISION OF CANCER CONTROL
A Division of Cancer Control has been created in the Bureau of Medical Services of the Maryland State Department of Health. Dr. W. Ross Cameron, Baltimore, Assistant Director of Welfare for Medical Care, and Dr. Howard W. Jones, Jr., Baltimore, Maryland, Division of the American Cancer Society, will assume joint responsibility for the development of a program including

Charles A. Janeway of Boston, Chairman of the Red Cross Advisory Committee on Blood and Blood Derivatives.

NUTRITION AWARDS

The American Institute of Nutrition made two awards at its annual dinner

statistical studies, educational activities, and the organization of adequate preventive diagnostic and treatment facilities.

OFFICE OF RECRUITMENT AND TRAINING IN CALIFORNIA

An Office of Recruitment and Training, with George T. Palmer, Dr. P.H., as coördinator, has been established in the California State Department of Public Health, San Francisco. The new unit will serve to coördinate the department's activities in this field. Dr. Palmer, who will be assisted in the administration of the office by an advisory board consisting of various staff members, has recently served as Senior Sanitarian, (R), U.S. Public Health Service, preceding which he was Associate Field Director of the American Public Health Association.

PROPOSAL TO PROVIDE GRANTS FOR POSTGRADUATE SCHOOLS OF PUBLIC HEALTH

Senator Robert A. Taft of Ohio, on June 17, introduced into the Senate of the United States a bill "to amend the Public Health Service Act to provide grants to postgraduate schools of public health." This bill would provide a sum to enable the Surgeon General to assist in improving the training available in the field of public health. The funds are to be used for the establishment and maintenance of teaching staffs, maintenance and operation of facilities, and scholarships for persons contemplating work in the field of public health. An additional appropriation is provided for the construction of buildings and other facilities, if necessary.

The appropriation for the operation of schools would be available on the basis of enrollment. The bill also provides that grants could be made only to those postgraduate schools of public health that are accredited by a board approved by the Surgeon General.

The bill was referred to the Committee on Labor and Public Welfare but no action was taken on it during the 80th Congress.

ENRICHMENT OF CORN PRODUCTS

The Food and Nutrition Board of the National Research Council at a meeting in May, 1947, adopted the following resolution with regard to the enrichment of corn products:

That universal enrichment of all corn products should be achieved as promptly as possible, especially in all areas of the United States where the average annual per capita consumption of corn products equals or exceeds fifty pounds;

That all states in such areas should adopt the federal standards for purposes of legislation concerning the enrichment of corn products;

That state and federal authorities should take immediate steps to foster the enrichment of all whole corn products produced within the borders of each such state;

That mandatory legislation requiring the enrichment of both whole and degerminated corn products should be enacted and enforced as soon as practicable in each such state.

The Board further directs that a copy of this resolution be sent to the Surgeon General of the U. S. Public Health Service and the Director of the U. S. Agricultural Extension Service for transmission to their officers and agents in the Southern States; to the presidents of the agricultural colleges of the South, to the commissioner of health of each Southern State, to the American Public Health Association, and to the Council on Foods and Nutrition of the American Medical Association.

Corn was first included as a cereal to be considered for enrichment by the Board in 1941 as a measure for the prevention of pellagra and other nutritional deficiencies in areas of high corn consumption. Such enrichment was endorsed as early as 1943 and a tentative partial enrichment formula proposed. Finally, early in 1946, it recommended nutrient levels in corn products corresponding substantially to those in effect for enriched flour. The issuance by the Federal Food Administration in

1947 of definitions and standards for enriched corn products gave further impetus to the promulgation of the Food and Nutrition Board's most recent resolution.

In order to develop plans for corn enrichment, the Board held a two day conference in mid-July at Clemson A & M College, Clemson, S. C. Here were discussed the most effective procedures for developing the enrichment program as well as the educational problems and techniques for establishing better public understanding of the need for enrichment. Clemson College for the past 3 years has demonstrated the feasibility of enrichment of whole corn meal in small mills and has led in developing suitable cheap machinery and usable enriching mixtures. Representatives were present at this conference from the 13 states from West Virginia to Oklahoma where the consumption of corn products is extensive enough to have public health significance.

NEW OFFICERS OF TWO AFFILIATED SOCIETIES OF A.P.H.A.

Arizona Public Health Association—

President—Margaret J. Maleady, R.N., Bisbee

President-Elect, O. V. Cooper, Phoenix

Vice-President, Clerks' Section—Eunice Ross, Bisbee

Vice-President, Health Officers Section—Paul W. McCracken, M.D., Phoenix

Vice-President, Laboratory Section—Mr. Bayless, Bisbee

Vice-President, Nurses' Section—Marjorie Fairley, Wilcox

Vice-President, Sanitariums' Section—Oscar V. Cooper, Phoenix

Secretary-Treasurer—Jefferson I. Brown, R.N., Phoenix

Utah Public Health Association—

President—LaVerna Peterson, Ogden

President-Elect—Frederic M. Kriete, M.D., Salt Lake City

Vice-President—James Z. Davis, M.D., Salt Lake City

Treasurer—Verle B. Lesnan, R.N., Salt Lake City

Secretary—Louis P. Gebhardt, M.D., Salt Lake City

WEST VIRGINIA PUBLIC HEALTH ASSOCIATION

At a recent meeting of the West Virginia Public Health Association, the following officers were elected for the year 1947-48:

President—L. A. Dickerson, M.D., Health Officer, Madison.

1st Vice-President—L. A. Lively, Sanitarian, Bluefield.

2nd Vice-President—Charlotte McLoughlin, Public Health Nurse, Kanawha County Health Department.

Secretary-Treasurer—Annette King, State Health Department.

HAWAII PUBLIC HEALTH ASSOCIATION

The Hawaii Public Health Association elects new officers:

President—Virginia Jones.

Vice President—Robert Horton, M.D.

Secretary—Katherine Walter.

Treasurer—Andrew Wong.

C. L. Wilbar, Jr., M.D., President of the Board of Health, was elected to the executive committee, with Virginia Doyle and Robert Lloyd.

CANCER INSTITUTE FOR PUBLIC HEALTH NURSES

The Ohio Division of the American Cancer Society, with the coöperation of the Ohio State Department of Health and the Western Reserve University School of Nursing, in June held a three day Cancer Institute for Public Health Nurses at the Cleveland Health Museum. Called on a state-wide basis, the Institute was designed to give public health nurses in the state a background of information and interest for sharing in the cancer control program.

VIRGINIA EXTENDS LOCAL HEALTH SERVICE

Announcement has been made by the Virginia Health Department of the addition of Surry County to the already existing tri-county health unit including Dinwiddie, Prince George, and Sussex Counties. The combined population of the four counties, without the inde-

pendent cities of Hopewell and Petersburg, which have their own health departments, is about 50,000. The Health Officer is Francis J. Clements, M.D.

Also reported by Virginia are the appointment of Walter R. Johnson, M.D., and Merle V. Bemis, M.D., respectively, as Health Officers of the Alleghany-Botetourt and Buchanan-Tazewell bi-county health units. Both of these districts have been without health officers for a number of months.

INDUSTRIAL HEALTH CONSULTANT SERVICE

Gordon C. Harrold, Ph.D., and Stuart F. Meek, M.D., formerly Chief Industrial Hygienist and Assistant Medical Director respectively for the Chrysler Corporation, and more recently independent consultants, with a group of associates have organized a confidential consultant service in the broad fields of industrial health, hygiene, and safety for individual clients.

Their organization is called the Industrial Health, Hygiene and Safety Service. Its headquarters are at 18221 Muirland Avenue, Detroit, Mich.

DRS. LANZA AND MELENEY DIRECT INSTITUTE OF INDUSTRIAL AND SOCIAL MEDICINE

Among the plans announced for the new fifteen and a half million dollar New York University-Bellevue Medical Center in New York City are plans for an Institute of Industrial and Social Medicine. According to an announcement by the University, the co-directors of the Institute will be Anthony J. Lanza, M.D., recently Associate Medical Director of the Metropolitan Life Insurance Company and formerly Colonel in the U. S. Army Medical Corps, and Henry E. Meleney, M.D., Professor of Preventive Medicine at New York University. In announcing the plan Dean Currier McEwen of New York Univer-

sity Medical School reported that this project would cost \$1,575,000 for laboratories, clinical facilities and administration. Among its features will be a general clinic to be opened in the fall of 1947 to offer wage earners a comprehensive plan of medical care. Dr. Lanza estimates that the annual loss to the nation in wages and medical expenses because of absences from work occasioned by illness approaches eight billion dollars.

GRANT FOR MULTIPLE SCLEROSIS RESEARCH

The Association for the Advancement of Research on Multiple Sclerosis has made its first grant, of \$64,350, for specialized research on multiple sclerosis. For a three year period, it will cover research in the field of allergy in relation to the disease. The research will be under the direction of Elvin A. Kabat, M.D., Assistant Professor of Bacteriology at Columbia University, and known for his research in specialized fields of medicine. His work will be done largely at the Columbia University College of Physicians and Surgeons and the Neurological Institute of New York.

BRUCELLOSIS CENTER ESTABLISHED AT FINLAY INSTITUTE

On March 10, 1947, the Finlay Institute, Havana, Cuba, established a new service to cover general investigation and the bacteriological quality of milk and the specific study of brucellosis. At the recent inauguration ceremonies, particular credit was given to Dr. Ramón Grau San Martín, President of Cuba and Dr. José R. Andreu, Minister of Health and Social Assistance, for their special interest and help in securing the establishment of these new activities.

MAINE'S NEW SECTION OF INDUSTRIAL HEALTH

A section of Industrial Health was established in the Maine Bureau of

Health in January. Its director is J. Elliot Hale who, in 1938, made a survey of the industrial health problem in the state. It was then found that many unsatisfactory working conditions existed. Consequently a program was planned of engineering, statistical, and educational services to Maine industries. Mr. Hale has been for many years Senior Sanitary Engineer in Maine's Division of Sanitary Engineering.

PERSONALS

Central States

LEROY L. FATHERREE, M.D., M.P.H.* Health Officer of Omaha, Neb., has been designated officially by Douglas County as County Health Officer. Dr. Fatherree will serve as Health Officer for the combined area.

THOMAS A. GARDNER, M.D., Assistant Public Health Director of the city of Springfield, Ohio, since last October, was appointed Director of Health recently.

FRANK H. JENNE, has been named Assistant Secretary of the Cincinnati, Ohio, Public Health Federation and will take up his duties on September 15. Mr. Jenne received his Master of Health degree from the University of Michigan in June, and will complete field training at the Training Center, Savannah-Chatham Health Department, Savannah, Ga., in September before taking up his position with the Federation.

JOHN F. SHRONTs, M.D.,† on April 1 began his duties as Medical Director of General Mills, Inc., Minneapolis, Minn. He had previously been Chief of the Division of Industrial Hygiene of the Illinois State Health Department, and is one of the authors of the *Medical Survey Report* of the bituminous coal mining industry recently published.

* Fellow, A.P.H.A.
† Member, A.P.H.A.

CORA M. TEMPLETON, R.N.,* Director of Public Health Nurses, Cleveland Health Department, retired as of June 30, after 34 years of service, 27 of them as director. CARRIE E. LEWIS, R.N.,† Assistant Director of Nurses in Tuberculosis Control since 1929, has been appointed Acting Director of Nurses.

PERCY T. WATSON, M.D., M.P.H.† formerly Director of Public Health District No. 1 with headquarters in Bemidji, Minn. was awarded the honorary degree of Doctor of Science by Carleton College, Northfield, Minn., at its commencement program, June 9, for his many contributions to international good will and human betterment. Dr. Watson was appointed Director of the Minneapolis Division of Local Health Services, effective July 1.

Eastern States

STANHOPE BAYNE-JONES, M.D.,* recently Dean at the Yale University School of Medicine, New Haven, Conn., and recently Director, Board of Scientific Advisors, Jane Coffin Childs Memorial Fund for Medical Research, has been appointed President of the Joint Administrative Board of New York Hospital, Cornell Medical Center, New York, N. Y., effective July 1 with offices at 525 East 68th Street.

LEVERETT D. BRISTOL, M.D., Dr.P.H.,* has resigned as Commissioner, Maine State Department of Health and Welfare, in which position he has served for the last 2 years. Thirty years ago he became Maine's first Commissioner of Health, before the State Departments of Health and Welfare were combined. For many years, he was active in New York City as Director of the Bellevue-Yorkville Health Demonstration, and as Health Director of the American Telephone and Telegraph Company. He is a past

president of the Public Health Association of New York City, and of the New Jersey Health and Sanitary Association.

JAMES E. BRYAN,[†] has resigned as Executive Secretary of the Medical Society of the County of New York, and Managing Editor of *New York Medicine* on September 1, to become Executive Officer of the Medical Society of New Jersey with headquarters in Trenton.

MONROE DAVIS EASTON, M.D., became Associate Professor of Bacteriology and Immunology in the Harvard Medical School on July 1. He had previously served 3 years in this department, and also as instructor in the Yale and Washington University Schools of Medicine. Since 1937 he had been a member of the staff of the International Health Division of the Rockefeller Foundation and Director of the Research Laboratory of the California State Department of Public Health.

JOHN EDWARD FARRELL,* Executive Secretary of the Rhode Island Medical Society and the Providence Medical Association was granted an honorary degree of Sc.D. at the June Commencement exercises of Providence College.

FRANK ROBERT FRECKLETON, M.D., M.P.H.,[†] who has recently finished his course in the Columbia University School of Public Health, has been appointed to the staff of the Rensselaer County Department of Health, Troy, N. Y.

DON M. GRISWOLD, M.D.,* District State Health Officer in charge of the Geneva District, retired May 31, completing 16 years of service on the staff of the New York State Department of Health. Dr. Griswold is author of a textbook *Outline of*

Epidemiology developed for use in teaching medical students and health officers. He is also author of many scientific papers on such subjects as epidemiology, public health administration, administrative control of tuberculosis, the control of typhoid carriers, control of measles, and whooping cough, and communicable diseases in the tropics.

LOWELL IBERG has been named Associate Director of the New York State Charities Aid Association. He has been with the Association since 1940, except for leaves to work with UNRRA and with the New York State Committee on Child Care.

L. E. KLING, M.D.,[†] who on July 1 completed 6 years service with the U. S. Public Health Service, was appointed Acting Medical Director of the Planned Parenthood Federation of America with headquarters in New York, N. Y.

RUSSELL H. KURTZ, Editor of the *Social Work Year Book* published by the Russell Sage Foundation, New York, N. Y., has resigned to become Executive Director of the New Hampshire Citizens Council for the General Welfare with offices in Concord, N. H.

W. C. SPRING, M.D., M.P.H.,[†] who recently completed his public health course at Columbia University School of Public Health, has been appointed Commissioner of Health of the newly-established Tompkins County Department of Health, Ithaca, N. Y., effective July 1.

Southern States.

CAROLINE H. CALLISON, M.D.,[†] former Health Officer for Greenwood and McCormick Counties, South Carolina, has returned to the State Board of Health after receiving her Master of Public Health degree from Columbia University, New York, N. Y., and has been assigned to the Charleston County Health Department.

* Fellow, A.P.H.A.

[†] Member, A.P.H.A.

BERNARD D. DAITZ,* formerly Major, Sanitary Corps., Medical Rehabilitation Service, Veterans' Administration Hospital, Oteen, N. C., has been appointed Assistant Executive Officer, Medical Rehabilitation Service, Department of Medicine and Surgery, Central Office, Veterans' Administration, Washington, D. C.

HARRY EAGLE, M.D., has been appointed Scientific Director of the National Cancer Institute and will be in charge of research. He has been with the U. S. Public Health Service since 1936 assigned to research activities at the Johns Hopkins School of Hygiene and Public Health. He is noted for research on an improved method of treating syphilis, and for work on the cause and cure of sleeping sickness.

CLARA C. JOEL FLEISCHER, M.D., has been named Director of Maternal and Child Health of the City Department of Health of Richmond, Va., a newly created post. She will develop a city-wide program of maternal, infant and preschool health.

T. PAUL HANEY, JR., M.D.,* on July 1 took office as Director of Maternal and Child Health of the Florida State Health Department. For the past 7 years he has been Health Officer of Jones County, Mississippi.

J. W. MOUNTIN, M.D.,* has been appointed Associate Chief, Bureau of State Services, U. S. Public Health Service. He was formerly Chief of the States Relations Division of the Bureau.

DAVID E. PRICE, M.D., Dr.P.H.,† who is a staff member of the Public Health Service serving with the Research Grants Division of the National Institute of Health, has been transferred to a related activity of the National Cancer Institute, Bethesda, Md., and is now in charge of the Research and Educational Grants Program of the Cancer Institute.

R. G. ROSS, M.D., was named Supervisor of the milk control program for the Oklahoma State Department of Health on June 16.

DANIEL H. ROWE, M.D., has been appointed Health Officer of the Administration Health Unit composed of DeSoto, Charlotte and Hardee Counties with headquarters at Arcadia, Fla.

R. L. SIMMONS, M.D., M.P.H.,† has resigned as Director of the Lauderdale County Health Department, Meridian, Miss., to accept a position as Head of the Department of Preventive Medicine and Public Health at the University of Louisiana School of Medicine, New Orleans, effective August 1.

ALFRED H. WIETERS,* formerly Senior Sanitary Engineer, U. S. P. H. S., Washington, has returned to his former position as Director of Public Health Engineering, Iowa State Department of Health, Des Moines, Iowa, effective July 1.

HAROLD M. WILLIAMS, M.D.,† formerly Director of the Department of Public Health and Welfare of Fort Worth, has accepted appointment as Assistant Secretary-Editor of the State Medical Association of Texas, Fort Worth.

Western States

MILDRED E. DOSTER, M.D.,† on September 1 began her new duties as local health officer of the Washington City-County, Iowa, Health Department, and director of one of the state health districts comprising 7 of the counties of Iowa. Dr. Doster was formerly Director of School Health Service in the Denver, Colo., public schools.

GORDON C. EDWARDS, M.D., has been named Director, Division of County Health Units, of the Oregon State Board of Health. He succeeds RICHARD H. WILCOX, M.D., who recently resigned to return to his former post

of Umatilla County Health Officer. The new County Health Units Director has been for the last year Director of the Venereal Disease Control Section, and will continue to supervise the activities of this Section until a new Venereal Disease Control Officer can be named.

ROY O. GILBERT, M.D.,† formerly Assistant Health Officer and Director, Bureau of Preventable Diseases, Los Angeles County Health Department, has been appointed Health Officer of the County, effective May 6.

EDWARD KUPKA, M.D.,† returns to the position of Chief, Tuberculosis Service, California State Health Department. He left in 1944 to become Medical Director of La Vina Sanatorium, serving as consultant to the department in the meantime.

WALTER B. QUISENBERRY,* former acting head of the Department of Public Health and Preventive Medicine at the College of Medical Evangelists in Loma Linda, Calif., was recently appointed Chief of the Bureau of Venereal Diseases for the Territorial Board of Health, Hawaii.

RUTH J. RAATTAMA, M.D., M.P.H.,* who for several years has been Director of the Division of Maternal and Child Health in the Idaho State Department of Health, Boise, has resigned effective July 1.

Death

STEPHEN A. KOWALCHIK, Principal Sanitary Engineer, New Jersey State Department of Health, died June 18. He joined the engineering staff of the Department in 1930.

A Future for Industrial Medicine*

LEONARD J. GOLDWATER, M.D., F.A.P.H.A.

*Professor of Industrial Hygiene, Columbia University, School of Public Health,
New York, N. Y.*

INDUSTRIAL medicine is in a state of flux. It appears to be approaching maturity, but as yet the ultimate pattern has not become fixed. Physicians, employers, and workers all have a stake in the future of industrial medicine, and all three, especially through their respective organized bodies, will play a part in determining the shape of things to come. At the present moment medicine and its allied professions are in a position to assume leadership in this field. If this is to be done it will be necessary to dispel some of the confusion which now exists and to have a clear idea of the objectives of industrial medicine as well as the methods of attaining these objectives.

SCOPE AND OBJECTIVES

Up to the present time, no satisfactory and generally accepted definition of industrial medicine has been proposed, although a number of authoritative organizations and individuals have stated what they consider to be its scope and objectives. The Council on Industrial Health of the American Medical Association, in a detailed state-

ment published in 1940¹ states that "Industrial health is an inclusive term, incorporating three major types of activity.

"1. Medical and surgical care to accomplish prompt restoration to health and earning capacity following industrial accident or disease.

"2. Prevention of disease or injury in industry by the establishment of proper control over industrial environment.

"3. Education of employees about healthful living, both in and out of the industrial environment."

In another part of the same statement the Council defines the scope of medical service to be provided by the medical department of an industry in the following terms:

"1. Regular appraisal of plant sanitation.

"2. Periodic inspection for occupational disease hazards.

"3. Adoption and maintenance of adequate control measures.

"4. Provision of first aid and emergency services.

"5. Prompt and early treatment for all illnesses resulting from occupational exposure.

"6. Reference to the family physician of individuals with conditions needing attention, coöperating with the patient and physician in every practical way to remedy the condition.

* Special Review Article prepared at the request of the Editorial Board.

"7. Uniform recording of absenteeism due to all types of disability.

"8. Impartial health appraisals of all workers.

"9. Provision of rehabilitation services within industry.

"10. The conduct of a beneficial health education program."

More recently the Council on Industrial Health has offered the following definition²: "Occupational Medicine deals with the restoration and conservation of health in relation to work, the working environment and maximum efficiency. It involves prevention, recognition and treatment of occupational disabilities and requires the application of special techniques in the fields of rehabilitation, environmental hygiene, toxicology, sanitation and human relations."

The American College of Surgeons in a recent publication³ states that "The purpose of Industrial Medicine has been and always will be fundamentally the same, namely, 'the adequate care of the health of the industrial worker.'" In amplification of this statement four basic objectives of industrial medicine are given:

"1. To ascertain, by examination, the physical and mental fitness of employees for work.

"2. To maintain and improve the health and efficiency of those already employed.

"3. To educate the worker in accident prevention and personal hygiene.

"4. To reduce lost time and absenteeism from illness or injury."

The concepts quoted above may be regarded as representing those of "organized medicine." There appears to be one important fundamental difference between the point of view of the American Medical Association and that of the American College of Surgeons. The former strictly limits the concern of occupational medicine to disabilities arising out of work while the latter appears to believe that industrial medicine is concerned with all of the health

problems of the worker, regardless of their origin.

It is interesting to note that Dr. Stanley J. Seeger, Chairman of the Council on Industrial Health of the American Medical Association, issued a statement in 1942⁴ which places him in agreement with the American College of Surgeons and at variance with his own council. Dr. Seeger outlines the objectives of industrial medicine as being, among other things, "to procure and maintain fitness for work through efforts applied to the worker as an individual" and "to reduce all loss of time, absenteeism, and short work spans in industry the cause of which may be *in any way* (italics ours) related to health." This concept has been carried a little further by another outstanding industrial physician, Dr. Dan Lynch, who says⁵: "I recommend that industry generously and for profit arrange adequate medical care for the sick as well as the injured before compelled to do it, with coöperation by organized medicine, without it, if necessary." Dr. Lynch is one of the few industrial physicians who have openly advocated complete medical care as a part of industrial medicine.

The Chamber of Commerce of the United States and the National Association of Manufacturers may be cited as examples of employer groups which have shown active interest in industrial medicine. Both of these organizations have accepted the ideas of the Council on Industrial Health of the American Medical Association in regard to the scope and objectives of industrial medicine and both have been actively engaged in stimulating the establishment of medical services in industry.

A number of individual employers have extended their industrial medical services to include general medical care for their employees, and in some instances for the families of the employees as well. The medical services provided

may be comprehensive or limited and the costs are usually defrayed in part by the employees on a prepayment basis. The more important plans of this type have been summarized by Stern.⁶

Activities on the part of organized labor during the past few years have been responsible for the introduction of an entirely new idea into the field of industrial medicine, namely, the inclusion of various types of health and welfare clauses in labor-management agreements. As a result, the union contract has become an important factor in industrial health since it may include provisions for such things as medical care, hospital expenses, and cash benefits in the case of illness. Many of the agreements between management and labor which provide for medical benefits originated during World War II when wages were frozen and the government permitted medical benefits to be granted by employers in lieu of wage increases. Now there is a tendency on the part of labor to attempt to preserve these agreements. Since the availability of medical care and the payment of cash benefits in the event of sickness have a distinct effect on the duration of illness and on the duration of absence due to illness, health and welfare clauses in union contracts must be regarded as falling within the field of industrial medicine. What influences, if any, the Taft-Hartley Bill will have on this type of activity remains to be seen.

Passing mention must be made of the role of government in industrial medicine. Most important is the enactment and administration of workmen's compensation laws. At the present time all states except one have enacted workmen's compensation laws. A second important function of governmental agencies is the provision of certain preventive services, that branch of industrial medicine known as industrial hygiene. Activities in this field have been greatly expanded during the past

ten years due largely to federal grants-in-aid made available to the states under the Social Security Act of 1935.

In summary, it may be said that the principal objective of industrial medicine is optimum health for all employed persons. This being the case, the scope of industrial medicine must be sufficiently broad to permit the attainment of this objective.

METHODS

While there is general agreement as to the objectives of industrial medicine and there are no irreconcilable differences in regard to its scope, there are wide divergences of opinion as to how the objectives are to be attained. The main issues in the controversy revolve around the functions of the various groups and individuals who are concerned with the different aspects of industrial medicine. Private practitioners, whether they be in general practice or specialists, physicians employed part time or full time in industry, certain physicians employed by governmental agencies and some employed by insurance companies and by labor unions may be mentioned among those who are involved in the practice of industrial medicine. Each one of these groups has its own set of interests and all of them must be given a voice when methods of practising industrial medicine are under discussion.

There is little doubt that the American Medical Association, as a national body and through its component state and county societies, is the most influential medical organization in the country. The great strength of the American Medical Association stems from its vast membership among private practitioners; therefore it is quite natural that in the basic philosophy of this organization the private practitioner is regarded as the key figure in any system or method of providing medical care. As applied to the practice of in-

dustrial medicine, this point of view is expressed as follows¹: "The full-time industrial physician, if present trends prevail, will be less and less a therapist and more and more an administrator of public health through the application of industrial hygiene. In that capacity he should assume a public health function and act as a case finder for the private physician and specialist, through whom the direct remedial service should be applied." This statement, taken in conjunction with the list of functions of medical service in industry (quoted above), means that the American Medical Association would restrict the activities of the plant physician to little more than case finding, sanitary inspections, health education, and first aid work. This point of view, if generally adopted, might lead to a number of undesirable effects. In the first place it is unlikely that very many promising young physicians would be attracted into a field having such a limited scope. If all treatments except first aid are to be given in the offices of private physicians, an unreasonable amount of productive time would be lost while the injured, but not necessarily disabled, employee is travelling to and from the doctor's office and awaiting his turn to be treated. This would place a serious financial burden on industry and would discourage the employment of industrial physicians. Certainly few employers could be made to see the point of hiring a physician one of whose main functions would be to send employees to other physicians whenever any medical attention other than first aid is needed.

There could be other undesirable consequences if the dictates of the American Medical Association were to be followed. Not infrequently a worker who has been injured or has become ill prefers to receive treatment from the industrial physician. To oblige him to go elsewhere for treatment is to deny him the fundamental right of free choice

of physician to the same extent as this right is denied when he is obliged to accept treatment from a physician chosen by his employer (as required under the workmen's compensation laws of many states). The divided responsibility, differences in opinion, and often conflicting interests between the industrial physician and the private practitioner frequently lead to unpleasant controversy and often operate to the disadvantage of the patient. The family doctor is usually unfamiliar with working conditions in the plants where his patients are employed and tends to accept without question statements made by a patient. This may lead him incorrectly to attribute symptoms to an occupational exposure or episode or to recommend a change of duty, a period of absence, or some other unwarranted procedure. Estimation of a worker's fitness to perform a specific job or to return to work following illness or injury can best be made by the industrial physician; nevertheless he will frequently find the family physician giving conflicting advice to the patient. These are but a few of the situations in which the industrial physician and the private practitioner may be at variance.

The American College of Surgeons disagrees with the American Medical Association in regard to the treatment of industrial injuries, stating that an adequate industrial medical service requires "efficient care of all industrial injuries and occupational diseases,"² as contrasted with first aid and referral to a private physician for further treatment as stipulated by the American Medical Association. In actual practice there are few if any industrial medical departments employing a full-time physician which restrict their therapeutic activities to first aid and the treatment of occupational diseases. Workmen's compensation laws hold employers legally responsible for providing medical treatment for em-

employees who are injured or become ill in the course of their work. When a part-time or full-time industrial physician is in attendance he is ordinarily the one who renders the bulk of the treatment.

The industrial hygiene activities of physicians in the employ of an official or voluntary health agency or of an insurance company have been generally accepted as proper and as not being in conflict with practitioners of medicine. As a matter of fact there is a small number of highly trained industrial hygiene physicians who are in private practice. There are so few of these specialists that they are hardly in a position to raise a voice of protest against their main competitor, the governmental health agency. Physicians employed or retained by labor unions to render medical care to union members and their families have not been the subject of any serious controversy, at least in recent years.

It is a well known fact that, of disability among employed persons due to illness and injury, at least 90 per cent is attributed to causes not directly related to occupation. If, as the Chairman of the Council on Industrial Health of the American Medical Association has said,⁴ one of the objectives of industrial medicine is "to reduce all loss of time, absenteeism and short work spans in industry the cause of which may be in any way related to health," it is incumbent upon the industrial physician to concern himself directly with the major cause of illness among workers, that is, the causes which are not directly related to the occupational environment. This does not necessarily mean that the physician employed by industry must undertake to render complete medical care to all employees and their families, although in certain instances this has been and is being done. It does mean, however, that methods must be found whereby divided responsibility for the

health of employed persons can be eliminated and whereby the efforts of the physician practising within the plant can be better coördinated with those of his colleagues in private practice.

THE CHANGING ORDER IN MEDICINE

It is apparent even to the most casual observer that the entire structure of medical practice is undergoing a number of changes. The traditional fee-for-service solo practice is no longer able to satisfy the demands of a large part of the public or of a large number of physicians. The inadequacies of the older methods have been admirably presented by the Committee on Medicine and the Changing Order of the New York Academy of Medicine.⁷ Outstanding among the newer developments have been first, the phenomenal growth of medical prepayment plans and, second, the extension of group practice.

Efforts on the part of employed persons to secure some measure of security against the financial burdens caused by illness go back to the days of the Friendly Societies in England and later to similar organizations in this country. Employee mutual benefit associations as we know them today originated about seventy years ago⁸ and from their early days included the payment of benefits in the event of sickness or injury. It has been estimated that at the present time there are approximately 600 mutual benefit associations in the United States covering about a million and a half employees.⁸ A number of labor unions have established sick benefit plans, the first in this country having been set up in 1859. The number of union members covered in this way has never been large and probably will diminish as other forms of sickness insurance become more popular. At the present time there are two forms of insurance against the costs of sickness which provide coverage for substantial numbers of employed persons. These are

the Blue Cross hospital service plans which had 25,000,000 subscribers in 1946, and group health, accident, hospital, and surgical plans which cover perhaps 10,000,000 subscribers.⁸ In both instances the subscribers represent employed persons and their dependents. The National Industrial Conference Board found in 1946 that the costs of this type of insurance were borne entirely by the employer for nearly half of the employees covered.⁹

According to the latest available figures, medical care plans of the service type organized for employed groups number somewhere between 100 and 150, and cover approximately 500,000 employees and 100,000 dependents.¹⁰ These service plans must be distinguished from the group health plans mentioned in the last paragraph which are of the cash indemnity type. The latter offer certain cash benefits in the event of disability due to illness or injury, while the former pay part or all of the costs charged by attending physicians. In most of these plans the premium payments are defrayed jointly by employer and employee, a few being financed entirely by the employee and a smaller number entirely by the employer. The number of persons covered by some form of health insurance indicates that not only the private practice of medicine but the practice of industrial medicine as well is being affected by the rapid extension of the health insurance movement.

When the many advantages of group practice are considered it is amazing that this form of medical practice has not been developed on a larger scale. There are, of course, many types of medical practice groups, but fundamentally they all represent a form of medical teamwork functioning for the benefit of both patient and physician. Since the future of industrial medicine is inseparable from that of medicine in general, it is natural to expect group practice to

be applied to the former in at least the same degree as to the latter. The same principle applies to prepayment for medical care and to all other current developments in the practice of medicine.

INDUSTRIAL MEDICINE AS A SPECIALTY

Certification by a "specialty board" has become a fetish in American medicine. It cannot be denied that the motives which activated the creators of the system of certifying specialists were worthy and there is no doubt that standards of postgraduate medical education and of medical practice have in many ways been raised as a result of this movement. Nevertheless it has now begun to appear as though a Frankenstein has been created and its progenitors are showing signs of concern over what to do with this unruly monster. If the policy of giving preferential treatment in hospital appointments and salary bonuses in government jobs to possessors of the coveted specialty board certificates, then each branch of medicine must adopt the policy of certification in order to compete with other branches for new medical talent. In other words, if any specialty is to survive as such it must offer some mark of distinction which will set those physicians who have had extended education or training in some way apart from those who are presumably less well educated or trained.

In the specialties which have created certifying boards to date there has been no great difficulty in establishing the requirements for certification. This is due to the fact that the sphere of activity in the respective specialties had become pretty well fixed. The contrary is true in the case of industrial medicine. The functions of the industrial physician have not yet been determined, consequently there must inevitably be great difficulty in setting up standards for specialty certification.

Several organizations have shown active interest in the problem of industrial medicine as a specialty. Among these may be mentioned the U. S. Public Health Service, the American Academy of Occupational Medicine, the American Association of Industrial Physicians and Surgeons, and the American Medical Association. The Chairman of the Council on Industrial Health of the last named group has had the following to say on the subject²: "First of all, we are convinced that occupational medicine is a distinct specialty which can be defined. Secondly we believe that it is important that a certification board be established in this specialty. It will do much to elevate the standards of practice in the field of occupational medicine." Undoubtedly, as Dr. Seeger has stated, the field of occupational medicine can be defined. Unfortunately, up to the present time nobody has successfully tackled the job, although a few attempts have been made. That of the Council on Industrial Health of the American Medical Association is as follows²:

"The principal components of occupational medicine are:

"1. Health conservation.

The physician in industry is expected to maintain and improve health, fitness and productive capacity through physical, mental and emotional appraisals, job evaluation and placement, health counselling, health education and through the application of medical and psychiatric technics to industrial human relations.

"2. Medicine and surgery.

Medicine and surgery in industry deal with occupational diseases and surgery of trauma including disability evaluation, rehabilitation and medico-legal aspects, control of preventable illness, the industrial implication of the medical and surgical specialties and emergency care.

"3. Environmental Hygiene.

Environmental hygiene is concerned with the detection and control of occupational exposures, general plant sanitation and house-keeping, personal hygiene of workers, accident prevention, the application of regulatory codes and factory inspection laws.

"4. Administrative methods.

Administration includes medical department planning and operation, integration with related in-plant functions, maintenance of adequate records and statistics and correlation with community medical, hospital and health services."

Certainly the Council on Industrial Health is to be commended for having put into writing many of the important components which go into the practice of industrial medicine. Unfortunately, the terminology in several places tends to be somewhat vague, and there appear to be some important omissions. Just what is meant by "physical, mental, and emotional appraisals" is not entirely clear. What sorts of "medical and psychiatric technics" are referred to and how they are to be applied require further elucidation. It would appear that health conservation is to be achieved without diagnosis and treatment of disease. It is not stated whether the control of preventable illness is to be limited to diseases arising in the course of employment or is to include all preventable diseases. No doubt the Council will be more specific on some of these points as its thinking progresses and as it receives the comments of other interested persons.

The American College of Surgeons has defined the field of industrial medicine by stating that³:

"An adequate industrial medical service requires:

"1. A definitely organized plan for the medical service.

"2. A definitely designated staff of qualified physicians, surgeons, and attendants.

"3. Adequate emergency, dispensary, and hospital facilities.

"4. Preplacement and periodic physical examinations—to be made only by qualified medical examiners.

"5. Efficient care of all industrial injuries and occupational diseases.

"6. Reasonable first aid and advice for employees suffering from non-industrial injuries and illnesses while on duty. For further professional care such employees should be

referred to their own private or family physicians.

"7. Education of the employee in accident prevention and personal hygiene.

"8. Elimination or control of health hazards.

"9. Adequate medical records, accessibly filed in the medical department under responsible medical supervision.

"10. Supervision of plant sanitation and all health measures for employees by the physician or surgeon in charge.

"11. An ethical and coöperative relationship with the family physician.

"12. The use of approved hospitals."

If industrial medicine (or occupational medicine) were to embrace only those functions listed by the American Medical Association and the American College of Surgeons it would cover a tremendous range and diversity of activities: physical, mental, and emotional appraisals, job evaluation and placement, health counseling and education, application of medical and psychiatric techniques, occupational diseases, surgery of trauma, disability evaluation, rehabilitation, medicolegal matters, preventable illness, detection and control of occupational exposures, sanitation, personal hygiene, accident prevention, planning and administration, records and statistics, community correlation, physical examinations, first aid. Obviously no one individual, without an inordinately long period of training, could become expert in such a variety of subjects. Before specialty certification in industrial medicine can be established, it will be necessary to decide which items in the above list must be mastered by the candidate.

An essential corollary to the setting up of specialty certification is the provision of facilities for graduate and postgraduate training. At the present time such facilities both for didactic instruction and field training are quite limited, but there are indications of growth. The task of the educator is made difficult first, by the great variety of subjects he must cover and second,

by the fact that there is no unanimity as to what subjects he should teach. There is a definite need for some agreement among educators as to the basic content of curricula designed to train specialists in industrial medicine. Until the field becomes better defined, the combination of training in internal medicine, traumatic surgery, and public health are suggested as desirable for an industrial physician.

A PATTERN FOR INDUSTRIAL MEDICINE

The statement that "the present is pregnant of the future" is as true today as it was when originally made by Leibnitz some 250 years ago. This being the case, one has but to examine the present situation in medicine in order to get a pretty good idea of probable future developments. Most significant among current trends is increased utilization of insurance methods for budgeting the costs of illness. A second important development is that of group medical practice. In general, the tendency is to plan for medical care rather than to trust to chance that illness will not occur. Preventive medicine, based on periodic examinations and early diagnosis, is commanding renewed interest.

Working people have learned that through collective action they are able to secure benefits, not only in wages and working conditions, but also in connection with medical care, which as individuals they might not be able to obtain. Both they and their employers have recognized that the employed group constitutes a suitable and convenient unit to which insurance against the costs of sickness can be applied. Employers in increasing numbers are appreciating the advantage of assisting their employees in maintaining health and in securing medical care. Proof of these statements is found in the phenomenal growth among employed persons of Blue Cross plans and of so-called group health and accident insurance.

with employers frequently bearing the cost entirely or in part.

The pattern which appears to be evolving in medicine is based on prepayment methods of defraying costs and group practice for providing service. This pattern is not new in the field of industrial medicine. A successful industrial prepayment medical plan has been operated by the Tennessee Coal, Iron and Railroad Company in Birmingham, Alabama, since 1913. A recent report⁶ indicates that this plan provides complete medical care for 33,000 employees and 120,000 dependents. Care is provided at the place of work, in the home, hospital, or clinic, by a medical practice group of 75 physicians, 12 dentists, and 111 registered graduate nurses. The costs are shared jointly by employer and employee. A similar plan has been serving the employees (and their dependents) of the Standard Oil Company of Louisiana at Baton Rouge since 1924, and during World War II a plan along the same lines was developed by the Kaiser-Permanente groups. At the present time there are well over one hundred prepayment medical care organizations which have had their origin in industrial corporations. Now that opposition on the part of organized medicine to the general principles of prepayment and group practice has been pretty well dissipated it is reasonable to expect that there will be significant developments along these lines.

Industry is interested in maintaining and improving the health of its employees as an essential in maximum production. Labor is interested in obtaining medical care of high quality at a cost within its means. The physician is interested in practicing high quality medicine and in adequate remuneration for his efforts. The combination of prepayment and group practice would seem to offer great possibilities for achieving these goals. Under such a system the

industrial physician will take care of those medical problems which can be most efficiently handled at the place of work, referring the more complicated cases to appropriate members of his medical group. The patient thus obtains the benefits of team work medicine without the disadvantages of divided responsibility. The illogical and undesirable situation of having one doctor responsible for illness resulting from work and another for non-industrial illness is eliminated. Small industrial plants can enjoy the same advantages as the larger ones by arranging for part-time services of a physician who belongs to a medical group. As long as physicians remain in control of the development of plans of the type indicated, they need have no fear of losing their independence or economic security. If, through negativism or lack of courage, they fail to assume constructive leadership, industrial medicine may find itself going backward instead of forward.

Planning for the Chronically Ill*

Joint Statement of Recommendations by the American Hospital Association, American Medical Association, American Public Health Association, and American Public Welfare Association

INTRODUCTION

THE conquest of many of the acute communicable diseases has focused increasing attention on chronic diseases¹ as the major causes of death and disability. Numerous communities are now awakening to their responsibilities for the chronically ill. In eight states and at least four cities, action to meet the problem of chronic illness has already been taken or is in the planning stage.²

There is a great need for comprehensive planning to insure that the widespread interest in chronic disease is channeled into sound and effective activity. Such planning requires the mutual coöperation of the agencies and professions most vitally concerned with the problem. For this reason, representatives of the American Hospital Association, the American Medical Association, the American Public Health Association, and the American Public Welfare Association have considered the experience already accumulated and have prepared this statement as a guide in the development of community programs. Although planning to meet the economic needs of the chronically ill is of vital importance, primary consideration is given here to the health and medical aspects of the total problem,

including prevention, research, treatment, and rehabilitation.

It is hoped that the general public, as well as legislators and members of the health and welfare professions, will find this statement a useful guide and stimulus to planning for the chronically ill.

EXTENT OF CHRONIC ILLNESS

Chronic illness affects nearly every family. It has been conservatively estimated that about 25 million persons, more than a sixth of the population, have a chronic disease.³ Some 7 million of these have appreciable disability from their illness,⁴ while 1½ million are invalids.⁵ The most important of the chronic diseases are heart disease, arteriosclerosis, high blood pressure, nervous and mental disease, arthritis, kidney disease, tuberculosis, cancer, diabetes, and asthma.⁶ Because special provisions have been made for patients with tuberculosis and mental disease, they are not included in the scope of this statement.

Each year chronic diseases cause nearly a million deaths, and are responsible for the loss of almost a billion days from productive activity.³ Appropriate action can prevent much of this staggering loss to our economy.

Although the prevalence of chronic diseases increases with age, and the progressive aging of our population is one of the factors responsible for the growing importance of the problem, it

* This report has been approved by the A.P.H.A. Committee on Administrative Practice, upon recommendation of the Subcommittee on Medical Care, and approved by the Executive Board of the A.P.H.A. It has been adopted as an Official Statement of the four associations.

must be borne in mind that chronic illness occurs at all ages. Fully one-half of the chronically ill are below the age of 45, and 16 per cent of them are under 25. More than three-quarters are persons in the productive years from 15 to 64.³

Chronic illnesses in childhood and adolescence are particularly important because they influence the period of growth as well as the entire period of adult life. They may have serious effects on the emotional development and social adjustment as well as the education of their young victims.

PREVENTION

The basic approach to chronic disease must be preventive. Otherwise the problems created by chronic diseases will grow larger with time, and the hope of any substantial decline in their incidence and severity will be postponed for many years.

There is a need to intensify health department programs to control chronic communicable diseases such as tuberculosis, syphilis, hookworm, and malaria. Accident prevention programs—in industry, on the farm, and in the home—should be greatly expanded to reduce the incidence of physical handicaps.

The promotion of optimal health throughout life is an important factor in the prevention of chronic illness. Child and school health programs need to be strengthened. Wide expansion of nutrition, mental health, and housing programs can have important effects in decreasing the incidence of chronic illness.

The success of programs to conserve the health of infants and children suggests the possibility of achieving effective health programs directed to adolescents as well as adults. The health programs of our high schools and colleges, including medical examinations and correction of defects, physical fitness and recreational programs, and

health education require intensive development.

The periodic medical examination of apparently well persons needs to be explored on a new basis, including selective laboratory and clinical examinations chosen for particular age, sex, geographical, and occupational groups. These include serology, chest x-ray, urinalysis, electrocardiography, ophthalmoscopic and other examinations.⁷

Industry and labor can play an important constructive role in this connection by encouraging health examinations of employees, including laboratory procedures, on a much larger scale than at present.

The recent development of special phases of the health examination, particularly in the fields of tuberculosis control and cancer detection, is especially noteworthy. The great interest shown by the medical profession and the public in chest x-ray surveys and in the establishment of diagnostic centers to examine apparently well persons for early signs of cancer represents a distinct advance in preventive medicine. It may well initiate a basic shift in emphasis in the medical care of adults comparable to that which has occurred in obstetrics and pediatrics, in which preventive supervision and examination of presumably well persons is a major requirement of good medical practice. There is a need to explore the practical possibilities of preventive examinations to discover all possible disease, making full use of the diagnostic aids developed by modern medical technology.

RESEARCH

Further advances in the prevention as well as the treatment of many chronic diseases are dependent on research. Although a good deal of research is now being carried on in chronic diseases, only a fraction of the total need is being met.

War experience in medical research

has made it clear that we must broaden our vision and think in terms of research planned and organized on a much larger scale than any now contemplated. This requires the training and support of a much larger corps of medical scientists, and the development of teams of research workers to carry forward coördinated programs. The greatest emphasis must be placed on those diseases which are the most important causes of death and disability, such as heart disease, high blood pressure, arteriosclerosis, arthritis, kidney disease, cancer, diabetes, and asthma.

Research institutes in chronic diseases, associated with clinical facilities, may well become the basic units of such a program. In New York City, the research services of the Goldwater Memorial Hospital have carried on important research in kidney disease, arteriosclerosis, malaria, and cirrhosis of the liver.⁸ In Illinois, the State Commission on the Care of Chronically Ill Persons is considering the advisability of developing a state supported university research institute for the study of chronic illness which would, in addition to suitable research facilities, provide beds for 200 patients and an outpatient service for 15,000 patients a year.⁹ The National Institute of Health is formulating plans for intensive laboratory and clinical research in heart disease, geriatrics, cancer, and mental disease.

There is a great need for administrative research, for more precise information on methods of providing the necessary services for the chronically ill. Basic research on some of the administrative problems is already being undertaken,¹⁰ but the field is a relatively new one and requires intensive study and development.

Research is also necessary in the social and psychological aspects of chronic illness. The influence of these factors in the development of specific chronic diseases needs to be more fully

determined, while the effect of chronic illness on the individual's social relationships needs further study.

MEDICAL CARE

In the past, the approach to chronic illness has been primarily concerned with institutional care for advanced stages of disease. There is need for a new orientation which places major emphasis on the early stages of chronic illness with a view to preventing or at least delaying the progress of the disease process.

Diagnosis and treatment of illness at its inception is essential to the control of chronic disease. Competent medical supervision, if brought into play early enough, can have an important preventive effect. The most dramatic expression of this fact is found in cancer control, where diagnosis of early symptoms and prompt treatment may be a life-saving measure. Early diagnosis and proper management of diabetes prevents the serious complications of infection, gangrene, and coma. Similarly, early diagnosis and treatment may prevent complications or prolong the lives of persons with heart disease, hypertension, rheumatic fever, peptic ulcer, and other chronic diseases.

The barriers to early competent diagnosis and treatment must be removed. This requires the construction of hospital and laboratory facilities to cover all our communities, with co-ordination of facilities to insure a maximum of diagnostic and therapeutic effectiveness for the individual patient. Health and medical agencies need to plan to fill the great needs for personnel as rapidly as possible. Means must be found to remove the basic economic barriers to early diagnosis and therapy.

Health departments, which have carried on excellent educational activities in communicable disease, should turn in increasing numbers to the larger field of chronic illness and teach

the public the facts about heart disease, cancer, diabetes, and other chronic diseases, with special emphasis on early signs and symptoms and the importance of early and continued medical supervision.

The concept of medical care must be broadened to include the social factors which play a vital role in the progress of chronic illness. Physicians have learned, for example, that it is not enough to cure a patient with minimal tuberculosis and send him back into the community. On the contrary, he must be observed carefully over a long period of time for signs of reactivation of the disease process. Even more important, the physician must draw on community-resources in order to change the patient's environment to prevent breakdown. If the patient's previous occupation called for strenuous physical exertion, he should be retrained for office work or some other light occupation so that he can live with his tuberculosis or other chronic disease. Occupational retraining and job placement are essential therapeutic and preventive measures.

Several general considerations should be borne in mind in planning to provide adequate medical care for the chronically ill.

First, the care of the chronically ill is inseparable from general medical care. While it presents certain special aspects, it cannot be medically isolated without running serious dangers of deterioration of quality of care and medical stagnation.

Second, major emphasis must be given to coördination and integration of services. The person who is chronically ill will receive the type of care which he specifically needs only if provision has been made for the highest possible degree of coördination. Since the medical condition of the chronically ill person is not static but changes with time, it is essential to develop smoothly

operating mechanisms for referral from one type of care to another.

Third, facilities for the care of the chronically ill should be planned for the community as a whole and not for the indigent alone. Chronic disease strikes all sections of the population, and the lack of facilities is as great for those who are able to pay as for those who are not. The facilities for chronic disease should be community institutions serving all sections of the population. They will in this way achieve a greater degree of financial stability because of the additional income from those able to pay, and will be able to furnish a higher quality of care.

Fourth, the services and facilities necessary for the medical care of the chronically ill require considerable and continuing financial expenditures in order to maintain the quantity and quality of care offered. Good medical care for chronic illness cannot be purchased on an "economy" basis.

Fifth, and most important, the goal of medical care is to maintain and restore the chronically ill as independent and self-supporting members of the community. Major emphasis should be placed on home and office care, with hospital care, convalescent care, and rehabilitation serving where possible to return the chronically ill to productive community life, and with nursing home facilities providing for those whose medical condition is such that they cannot remain in their home environment.

HOME CARE.

The majority of persons who are chronically ill can best be cared for in home, office, and clinic.

It is unwise as well as impractical to consider a separate home, office, or clinic service for the chronically ill; their needs are best met by inclusion in the general community medical care program.

Ready access to diagnostic and specialist service is essential to adequate care for chronic diseases, since many of them are difficult to diagnose and treat.

One of the most pressing needs is for an expansion of public health nursing service to provide bedside and other nursing services for the chronically ill. Most rural communities and small cities do not have sufficient public health nurses to provide adequate bedside nursing care. Some of the larger cities have well organized bedside nursing programs, but even here the number of nurses is generally below the estimated minimum of one nurse per 2,000 persons to carry out all public health nursing activities including bedside care.¹¹ In addition to increasing the number of public health nurses, there is need to train them to provide valuable assistance to physicians in the time-consuming task of educating the individual patient in the proper understanding and management of his chronic illness.

Much wider use should be made of practical nurses and nurses' aides, working under the supervision of the public health nurse, for duties which do not require the training and experience of a graduate nurse.

Housekeeper service should be widely encouraged; there has already accumulated ample experience to show the value of the visiting housekeeper in the home care of chronic illness.¹² Housekeeper service performs the important social function of enabling the chronically ill patient to remain at home, and has an economic value in helping to reduce the need for expensive institutional facilities.

Other measures which enable chronically ill persons to be cared for at home include improved housing, supervised boarding homes, medical-social service, recreational and occupational therapy, and vocational rehabilitation. Social security measures to maintain income

such as disability insurance, old-age insurance, and public assistance are likewise of vital importance.

HOSPITAL CARE

The large number of chronically ill persons in general hospitals who require long-term care represents a serious problem to hospital administrators.¹³ The general hospital as at present constituted is often unsuited to the care of long-term patients, since it is geared primarily to the therapeutic and general requirements of the acutely ill. It may lack adequate departments for physiotherapy, occupational therapy, and rehabilitation, as well as sun porches, recreational facilities, educational facilities for children, and an understanding of the social and psychological needs of the chronically ill.

The average long-term patient requires less costly care than that provided in the acute general hospital.¹⁴ To continue to care for the long-term patient in the acute general hospital is wasteful; it provides care which is more expensive than he actually needs, and which is often unsuited to his requirements.

The construction of hospital facilities for the chronically ill has been encouraged by the passage of the Hospital Survey and Construction Act, which provides federal aid for such facilities up to a maximum of two beds per 1,000 population.¹⁵

There is already evident a tendency in some localities to build chronic disease hospitals in areas remote from the medical center and the general hospital and with no relation to them. This trend unfortunately follows the pattern already laid down in the construction of our tuberculosis and mental hospitals, a pattern which has resulted in many instances in the medical isolation and stagnation of these special institutions.

Hospital facilities for long-term illness should be built in the very closest re-

lation to teaching centers and general hospitals.

The specialized chronic disease hospital is suitable in large cities, where it can be located on the grounds of or very closely related to a medical school or teaching general hospital. Special consideration should be given to planning the facilities for children who are chronically ill. While an official or voluntary organization may be responsible for the construction and maintenance costs, the medical school should provide the attending and resident staff and utilize the facilities for research and medical education in chronic disease.

It is important that the specialized chronic disease hospital serve as the consultation center for chronic disease in its medical service region.¹⁶ It should maintain formal professional affiliation with general hospitals in the region that care for chronic patients, in order to provide consultation and teaching visits from the center to the general hospitals as well as the referral of patients to the center for special study.

Most patients with chronic illness who require hospitalization are best cared for in a unit of the general hospital especially designed to meet their needs. This arrangement encourages patients to seek and use care since it is near their homes, families, and friends; makes available to them the existing facilities of general hospitals; provides opportunity to internes, nurses, and staff for experience and teaching in chronic disease; avoids expensive duplication of existing general hospital facilities; and affords the most ready means of transfer to and from the acute and chronic disease sections of the hospital when needed. Further, it allows for greater flexibility in hospital planning by making it possible for future, unforeseen shifts in the relative proportions of patients with acute and chronic diseases to be met by changing the designated use of either chronic

or acute beds in the same hospitals.

Many advantages of this plan would be lost if the chronically ill were simply intermingled with all other patients in general hospitals. The provision of a special wing or floor devoted to long-term patients insures that the special needs and problems of chronic disease are not lost sight of in competition with the more urgent and dramatic needs of the acutely ill. It makes possible the planning of the special unit in conformity with its special purpose, both as to architecture and staff. It makes it easier to provide occupational and recreational therapy, special physical therapy, rehabilitation and other services essential to the care of long-term patients. It facilitates a more economical use of nursing personnel, the utilization of a larger proportion of attendants, and less intensive medical staff attendance than is needed in the section of the hospital devoted to patients with acute illnesses.

Under no circumstances should chronic disease hospitals or units be limited to the indigent. The lack of facilities is felt by all sections of the population. High standards will be maintained most effectively if the facilities are geared to meet the requirements of the entire community. Also, the admission of patients who are able to pay will reduce the need for tax funds. It must be recognized, however, that prolonged illness exhausts the financial resources of many patients, necessitating payment from tax funds for their care.

CARE IN NURSING HOMES

Chronically ill persons who need active and continuous medical care should be treated in a hospital. On the other hand, there are many chronically ill persons who are more or less disabled by their illness, whose requirements for care can be met by practical nurses and attendants with medical and nursing

supervision, and who cannot or should not remain at home. Care for such persons should be provided in nursing homes.

The following example may make the difference clear. A person who has suffered a cerebral hemorrhage with paralysis of one side of his body requires hospital care. This care will extend over a period of weeks and months, during which time he will receive intensive physical therapy to restore the maximum possible use of his muscular system. When no further improvement can be obtained by medical treatment, and he is left with a good deal of disability which makes it impossible for him to be cared for at home, he is eligible for care in a nursing home.

Nursing homes, both private and public, should be brought under state licensure laws in which provision is made for minimum standards and regular inspection. The minimum standards should require continuing medical supervision, including complete medical examinations of patients prior to admission to the nursing home and follow-up examinations at definite intervals, as well as physician visits on a regular basis and on call. The standards should call for a sufficient number of practical nurses and attendants to meet the full needs of the patients. They should provide for at least one full-time graduate nurse in charge of nursing care.¹⁷ The standards should require facilities for recreation and occupational therapy, for a maximum of privacy and individual attention, and for cheerful and homelike surroundings. Construction should meet adequate standards of safety and sanitation.¹⁸

Private Nursing Homes

Experience has demonstrated that improvement in the quality of private nursing homes cannot be obtained merely by passage of a licensure law. The power to inspect and license

nursing homes carries with it the responsibility for carrying on an intensive educational campaign, working with the individual nursing homes to improve the care given. The device of placing each new nursing home on a six month probationary period, during which time there is a great deal of educational assistance from the licensing agency, has been demonstrated to be an effective method of raising standards.¹⁹

It is suggested that wherever possible, the quality of medical and nursing supervision can be greatly improved through arrangement with the medical board of a nearby hospital to provide the necessary medical services.

One of the most serious drawbacks to adequate care by private nursing homes is the low payments made by welfare agencies for clients requiring nursing home care. A sharp upward revision of payments by welfare agencies, to bring them up to the actual cost of care, is an indispensable prerequisite to raising standards. At the federal and state levels, liberalization or elimination of the ceiling on payments for public assistants clients is indicated.

Public Nursing Homes

The realization that a large proportion of the population of county homes or almshouses consists of chronically ill adults has led to a widespread movement to convert them into public nursing homes.

It is clear that such conversion does not make the almshouse a chronic disease hospital, but rather a nursing home for the chronically ill.

County homes should be converted into public nursing homes only if their physical facilities are adequate, if they are within reasonable distance of general hospitals with which close medical relationships are maintained, and if the responsible authorities are prepared to meet the minimum standards described previously: namely, adequate medical

and graduate nursing supervision; sufficient personnel to meet the full needs of the patients, including medical-social service if possible; provision for privacy, a cheerful and homelike atmosphere, recreational and occupational therapy; and construction which meets safety and sanitation requirements. Many county homes cannot meet these conditions and should therefore not be considered for conversion.

It is suggested that conversion be planned on a state-wide basis, with the most careful evaluation of the suitability of individual almshouses for conversion. Financial and technical assistance by the State to localities planning conversion will make it possible to achieve higher standards of care. Public nursing homes should be included in the provisions of nursing home licensure laws.

A factor which will help obtain increased community interest, better administration, and higher quality care in public nursing homes is the admission of patients able to pay part or all of the cost of care. There is a considerable demand for public nursing home care on the part of patients able to pay. By opening its facilities to such patients the public nursing home will not only improve its financial position but will perhaps begin to free itself from the almshouse tradition and serve as a public facility for the entire community.

The Social Security Act should be amended to allow federal matching to states for assistance to patients who wish to enter public medical institutions, including nursing homes, that meet adequate standards. Payment for nursing care in public as well as private homes should be commensurate with the actual cost.

New Institutions

The shortage of institutions for nursing home care of the chronically ill cannot be met by present facilities or

by the conversion of county homes. There is a definite need for new construction.

It is recommended that voluntary and governmental general hospitals which have chronic disease pavilions give serious consideration to establishing nursing home facilities for the chronically ill. These facilities should be built on the grounds of the general hospital or within a reasonable distance. There should be close administrative, medical, and nursing relationships between the hospital and the nursing home.

The specialized chronic disease hospitals located in teaching centers should likewise maintain nursing homes which can be utilized for research and training and will set standards of quality of nursing home care.

The construction of new institutions should be closely integrated with state plans for reconversion of public homes and utilization of private nursing homes in order to prevent an overabundance of facilities in some areas and lack of facilities in others.

CONVALESCENCE AND REHABILITATION

Undoubtedly the most neglected aspect of chronic illness is that of convalescence and rehabilitation.

Only recently has there been recognition of the fact that convalescent care is an important feature of the care of the chronically ill. Chronic diseases often run a course of many years, with periods of relative well-being alternating with periods of illness. Following a flare-up of illness adequate convalescent care may lead to complete or partial rehabilitation, and may help delay the progress of the underlying chronic disease. Such convalescent care undoubtedly conserves hospital beds and performs important therapeutic and preventive functions. Examples of chronically ill persons requiring convalescent care would include those recovering from a period of heart failure.

an attack of acute rheumatic fever, or a flare-up of arthritis. Then there are persons who have a chronic illness such as diabetes or heart disease, and develop pneumonia or some other acute illness, and need convalescent care after recovery from the acute illness.²⁰

There has been a large growth of convalescent homes for children with rheumatic heart disease and other crippling conditions. It is essential that such convalescent homes be located near enough to general hospitals to permit close professional relationships and adequate medical supervision.

Convalescent homes for adults have never been developed to any appreciable extent in the United States. Most convalescent care for adults is now provided in nursing homes which also care for non-convalescent patients. On the whole, there has been insufficient appreciation of the value of convalescent care and rehabilitation in the care of the chronically ill.

Recent experience with planned convalescence and rehabilitation in the armed forces has demonstrated their great potential usefulness. By providing physical reconditioning, educational training, recreational activities, and vocational guidance, it was found possible to shorten the period of hospitalization, reduce the incidence of recurrences, and return a larger proportion of men to active duty.²¹

Planned convalescence and rehabilitation are particularly important in chronic disease. The chronically ill have to be made conscious of their limitations early in the course of the disease, and many of them must be retrained for new occupations so that they may stay within the limits of activity prescribed by their illness and yet maintain their economic independence.

Probably the first steps along these lines will be taken by university hospitals, some of which have already made plans for rehabilitation centers as an

integral part of their medical program.

In 1943, Congress broadened the scope of the national rehabilitation program. As a result, state rehabilitation agencies were able to rehabilitate successfully nearly 42,000 persons in 1945. These were generally persons with long standing chronic impairments and illnesses—orthopedic disabilities, speech, hearing, and sight defects, poliomyelitis, tuberculosis, mental disease, heart disease, asthma, hernia, and other conditions.²² That the need is still far from being met is indicated by the fact that the estimated backlog of persons in need of and entitled to such service is between 1½ and 2 millions.²³

Of the 42,000 disabled persons who were successfully rehabilitated in 1945, nearly 79 per cent were unemployed at the time of applying for rehabilitation service, and 18 per cent had never been employed. The average yearly income before rehabilitation, including those who received assistance from public or private sources, was \$288. The average annual wage after rehabilitation was \$1,764. The total income of the group was increased by rehabilitation from 12 million dollars a year to 74 million, a sixfold increase.

In the past, many of the disabled have had to be supported by public or private assistance at a cost up to \$500 a person each year. Vocational rehabilitation costs an average of only \$300 a person, and this cost is not repeated.²² On the contrary, rehabilitation changes the individual into a self-sustaining productive member of the community. It is clear that rehabilitation is economically and socially sound.

The results achieved with long standing chronic impairments and diseases point up the great potentialities of rehabilitation instituted early in the course of chronic illness.

COORDINATION OF SERVICES

The problem of chronic disease pre-

sents many aspects—prevention, research, medical care in home, hospital and nursing home, and convalescence and rehabilitation.

Undue emphasis on any one aspect would be unwise, uneconomical, and ineffectual. For example, to concentrate on the provision of medical care without paying serious attention to prevention and research would postpone for many years any basic attack on the problem. On the other hand, it is impossible to focus sole attention on research because of the very urgent need for medical care. Likewise, to provide hospital beds for chronic disease without making nursing home facilities available would result in many beds being occupied by patients who do not need hospital care. Too great an emphasis on nursing homes would deprive many patients of the specialized hospital care which is necessary for their improvement. Failure to plan adequately for home care or for convalescent care and rehabilitation would defeat the purpose of the program—to maintain and restore the individual as a self-supporting productive member of his community.

There is a great need for coöperation and coördination of the numerous agencies concerned with chronic disease: health, welfare, and education departments, hospitals, medical societies, medical schools, social agencies, rehabilitation services, nursing homes, etc. In some communities this coördination has been achieved through the establishment of central planning and coördinating bodies which study the various aspects of the problem, make the facts known to authorities and the public, stimulate needed services, assist in securing necessary facilities, and act as information centers for patients, physicians, and health and social agencies.²⁴

The total problem of chronic disease is not a series of separate problems which can be solved one by one, but

rather a complex of interrelated problems which require simultaneous solution. It is recommended, therefore, that coördinated and comprehensive planning be undertaken at all levels in order to achieve effective action to meet the challenge of chronic illness.

REFERENCES

1. The term "chronic disease" is susceptible to various definitions. An administrative definition of chronic disease has been suggested as follows: "A disease that may be expected to require an extended period of medical supervision and/or hospital, institutional, nursing, or supervisory care." (Rogers, E. S. Chronic Disease: A Problem That Must Be Faced, *J.P.H.*, 36:345 (Apr.), 1946.) In the National Health Survey, chronic disease was defined for statistical purposes as "a disabling or non-disabling chronic pathological condition known to the informant, the symptoms of which had been recognized for at least three months." (Perrott, G. St. J. The Problem of Chronic Disease, *Psychosom. Med.*, 7:22 (Jan.), 1945.) Another definition is that used for survey purposes by the Public Welfare Council of Connecticut, "A disease or condition of the body or personality which has been present at least six months or which may be expected to continue at least six months and which interferes with one's occupation and normal physical and social life." (*Need for a State Infirmary for the Care and Treatment of Aged, Infirm, and Chronically Ill Persons*, Public Welfare Council, Hartford, 1944, p. 4.)
2. The states referred to are California, Connecticut, Illinois, Indiana, Maryland, Massachusetts, New Jersey, and New York. The cities are Chicago, Cleveland, Milwaukee, and New York.
3. Perrott, G. St. J. The Problem of Chronic Disease. *Psychosom. Med.*, 7:22 (Jan.), 1945. The estimates given are admittedly low because of the survey technique used.
4. National Health Survey, *Some General Findings as to Disease, Accidents and Impairments in Urban Areas*. *Pub. Health Rep.*, Reprint No. 2143, p. 2 ff. The frequency of chronic illnesses causing disability of at least seven consecutive days in a 12 month period was found to be 48 per 1,000 persons, or approximately 7 million for the total population.

13. The percentage ranges from 7 to 20 per cent.

depending on the area surveyed. In New York City, in 1928, a fifth of the ward beds in both private and municipal general hospitals were occupied by chronic patients. (Jarrett, M. C. *Chronic Illness in New York City*, Columbia Univ. Press, 1933, Vol. 1, p. 119.) In New Jersey, in 1940, 38 general hospitals reported that 7 per cent of the total number of patients were chronically ill. (Frankel, Emil. *New Jersey Studies Problems of Care for the Chronically Ill*. *Hospital Management*, 50:19 (Aug.), 1940.) The findings to date in the Illinois State Health Department's survey of hospital facilities indicate that about 15 per cent of the beds in the general hospitals of the state are occupied by chronically ill patients (unpublished data).

14. The cost at Montefiore Hospital, a high standard voluntary chronic disease hospital in New York City, is more than two-thirds the cost in acute general hospitals. (Communication from Dr. E. M. Bluestone, Director.) In 1945, the cost at Goldwater Memorial Hospital, a municipal chronic disease hospital in New York City, was one-half the average cost in the acute general municipal hospitals (Communication from Dr. E. M. Bernecker, Commissioner of Hospitals of New York City).

16. *Planning for the Care of the Chronically Ill in New York State—Regional Aspects*. New York State Health Preparedness Commission, Albany, 1946.

Health Service Areas, Pub. Health Bull. No. 292, U. S. Public Health Service, Washington, 1945.

17. The present shortage of nursing personnel

makes it impossible in many instances to meet this requirement. The New Jersey State Department of Institutions and Agencies has met the situation by helping nursing home operators to make arrangements for a daily supervisory visit from the local visiting nurse association. The plan seems to be working very well.

18. A detailed description of minimum standards of nursing home care is given in *Institutional Care of the Chronically Ill*, a report issued by a joint committee of the American Hospital Association and American Public Welfare Association in January, 1940.

AMERICAN PUBLIC HEALTH ASSOCIATION

Uses of Statistical Data in State Health Departments*

ELLEN B. WHITEMAN, M.P.H.

Statistician, The Commonwealth Fund, New York, N. Y.

STATISTICAL work being carried on in state health departments in 1940 was studied by Mountin and Flook, several years ago, for the preparation of a revised edition of *Public Health Bulletin No. 184*. Their findings indicate that all state health departments were making simple tabulations of vital statistics data; many were prepared to supply certain statistical information upon request; and about one-third were routinely preparing certain descriptive material for use by other divisions, such as lists of tuberculosis deaths. The authors of this report were, for various reasons, forced to conclude, however, that "few states go beyond their primary duty of collecting and preserving records and preparing more or less standard tabulations."¹

In the few years since that study, many state health departments have taken steps to expand their statistical services. Much of this expansion has been stimulated by increased federal and state activities in special fields, such as tuberculosis control, venereal disease control, and the Emergency Maternity and Infant Care program.

In April, 1946, information on statistical services now being rendered and the types of administrative organization for giving these services, was obtained

by questionnaire from 42 state health departments.[†] All 42 states, as in the past, were making more or less standard tabulations of data from birth and death certificates. Recent expansion of statistical activities into new fields was evident, however, from the replies received. Health departments in 29 states reported statistical work in progress in the field of communicable diseases (including morbidity reports), 26 in tuberculosis control, 22 in venereal disease control, and 14 reported statistical work being carried on with data accumulated through the Emergency Maternity and Infant Care program. These, and other fields of statistical activity, with the numbers of states so engaged, are shown in Table 1. The nature and extent of statistical work in each of these categories varied widely. Activities which were reported in the field of communicable disease control for example, varied all the way from a simple weekly tabulation of notifiable diseases in some states to research by one state health department on the effect of ultra-violet irradiation on transmission of disease due to filtrable viruses. Likewise, statistical work in tuberculosis control included a range of projects from the comparatively simple procedure of maintaining a central register of known cases to the scientific research required for the epidemiologic study of familial susceptibility to tuberculosis.

In general, the statistical work being conducted in state health departments falls in three classifications.

* Presented before the Vital Statistics Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1946.

[†] No reply was received from Connecticut, Georgia, Minnesota, Pennsylvania, Utah, and Wyoming.

* Information obtained from questionnaires sent each state health officer.

1. Simple tabulation of data collected routinely in the various divisions and services of the health department
2. Statistical analysis of data collected routinely
3. Independent investigation and research in specific problems relating to public health.

All state health departments are engaged in the first of these, that is, current tabulation of data collected routinely. In this category are such items as periodic activity reports, morbidity reports and tabulations of data on death certificates. Not all state health departments, however, are utilizing this information, by means of statistical analysis, for the full advantage of the various public health programs.

Very few state health departments are engaged in statistical research in specific fields—the third type of activity mentioned above. This type of work requires, in addition to specialists in the field concerned, the services of an expert statistician. Outstanding work of this last type was reported from 3 states. Massachusetts is carrying on cytologic research in the evaluation of the vaginal smear technique for the diagnosis of uterine cancer in symptom-free women, and a study of the genetic-environmental factors pertaining to cancer. This department in addition conducts studies on the relation of industrial environment

to health, and a study of fluorine as a preventive of dental caries. The New York State Health Department is also studying the effect of fluorine on the incidence of dental caries, and the effect of ultra-violet irradiation on the transmission of diseases due to filtrable viruses, which was mentioned above. In Tennessee, research has been carried on since 1931 in the epidemiology of tuberculosis, with intensive study of such factors as the prevalence of infection in racial groups, morbidity and mortality in households, familial susceptibility to tuberculosis, and the significance of sensitivity to histoplasmin and tuberculin.

Research of this type, obviously, depends upon the availability of highly trained personnel. While many state health departments may be unable to carry on a research program on a permanent basis, all state health departments can obtain personnel capable of analyzing the information collected routinely for the evaluation of programs and program planning. This activity is, perhaps, the primary purpose of a statistical unit in a state health department.

For many years, state health departments have been publishing tabulations of data from birth and death certificates. Such tabulations frequently fill several

PERCENTAGE DISTRIBUTION BY AGE OF INFANT DEATHS FROM PREMATURITY MISSISSIPPI, 1943

pages in annual departmental reports, where they undoubtedly rest in peace. When the data are subjected to even the simplest type of statistical analysis, however, they can be made to answer questions pertinent to specific health problems. One example of this use of statistical data is in connection with the planning of a whooping cough immunization program. In the early part of 1942, the Tennessee Department of Public Health, with the assistance of the Commonwealth Fund, began making plans for an active program of immunization against whooping cough. The disease had been recognized as constituting a major health problem among young children and with the development of an effective vaccine it had become possible to talk in terms of prevention. Analysis of the data on mortality and morbidity in the area indicated the age groups in which immunization was most needed. Table 2 shows that whooping cough case rates, death rates, and case fatality rates were very high for children under 5 years of age. Moreover, the greatest risk of death was for very young children. Of all those dying of whooping cough in Tennessee in the 5 year period 1938-1942, 93 per cent were less than 3 years of age, 86 per cent were less than 2, and 62 per cent, or nearly two-thirds, were less than 1 year of age. Hence, if the immunization program were to lower morbidity and mortality from whooping cough, vaccinations would have to be given as early in life as practicable and concentrated on the age group under 3 years of age. This was actually the program inaugurated.²

Another use of information currently obtained from vital statistics records is illustrated by a study of infant deaths, such as one prepared by the Mississippi State Board of Health. It was evident from this work that the various specific causes of death covered by the term "prematurity" were a challenge to med-

ical and public health personnel. Of 2,774 deaths of infants under 1 year of age in Mississippi in 1943, 625 or 22.5 per cent were said to have died from "premature birth." Chart 1 shows that 63 per cent of these deaths occurred when the infant was less than 1 day old, and an additional 23 per cent occurred between the ages of 1 day and 1 week. Thus, 86 per cent of the deaths occurred in the first week of life. If the death rate in the age group under 1 year is to be reduced, therefore, emphasis must be placed first on the best possible care of mothers in the antepartum period, in order to prevent delivery before term, and on the best possible care of the immature new-born. Accordingly, with this in mind, the Mississippi State Board of Health, in 1945, held short wartime postgraduate courses in pediatrics and obstetrics which were attended by one physician out of every five in active practice in the state.³ Another important phase of this program is the provision of incubators in county health departments throughout the state which are available for loan whenever needed for care of the new-born.

A third illustration has to do with the use of information from a different type of record. When many questions arose with regard to a need for modification of the school health program in Tennessee, several years ago, the existing public health service records were used as a basis of judgment.⁴ Analysis was made of the findings on physical examinations recorded on the school health records of about 58,000 children in 6 counties. One of the many items considered was the result of vision tests. Study of vision tests at first examination showed a gradual increase in the incidence of visual defects from 2.3 per cent for 6 year old children to 6.9 per cent for 16 year olds. The data are given in Table 3 and Chart 2. It was also shown that the percentage of children found with visual defects for the first time was

TABLE 3

Percentage of School Children with Vision Defects at First Examination, By Age, 1930-1936
(Six Tennessee Counties) *

Age at examination	Children examined	Children with vision defects	
		Number	Per cent
Total	54,487	2,147	3.9
6	11,183	255	2.3
7	10,187	301	3.0
8	6,910	261	3.8

* From *School Health Services*, by Walker and Randolph †

CHART 2

PERCENTAGE OF SCHOOL CHILDREN WITH VISION DEFECTS AT FIRST EXAMINATION, BY AGE

DATA ON SIX TENNESSEE COUNTIES, 1930-1936. FROM *SCHOOL HEALTH SERVICES*, BY WALKER AND RANDOLPH

practically, the same on first, second, third, and fourth examinations. Since the attack rate of visual defects was fairly constant for all ages and since the prevalence of defects increased with age, the examination of children at any

one time obviously would not discover all vision defects. For this reason, the authors concluded that although a first examination of school children would, for example, reveal the bulk of heart and lung defects, annual vision tests of

all children at all ages would be needed to detect visual defects as they occurred throughout the school years.

Studies such as these just described are needed for intelligent planning by health administrators and are the mark of the mature health department. There is evidence that public health officials now more than ever realize the need for statistical evaluation of work as it is being carried on in the various fields of public health. Some progress has already been made toward establishing the necessary administrative machinery for doing so. Ten states, of the 42 submitting information to the questionnaire described above, reported that they had centralized statistical units which could render statistical service to all divisions of the health department. These states were: California, Illinois, Indiana, Louisiana, Michigan, Mississippi, Oklahoma, Tennessee, Washington, and Wisconsin. Administrative organizations for statistical work in these 10 states differ in one important respect. Five departments have organized central statistical services which are administratively independent of registration of birth and death certificates. In these services, the chief statistician is directly responsible to the state health officer. The other 5 state health departments have organized bureaus (or divisions) of records and statistics which are divided into two sections, one for registration and one for tabulation and analysis. The ways in which these two types

of organization are coordinated with other divisions of the health department have been described in detail by Linder.⁵

In addition to the 10 states with central statistical services already organized, six states reported in April, 1946 that they were planning to organize this type of service in the near future.

For the sound development of statistical organization in a state health department, one question is paramount: By means of what type of organization can the mass of public health data be most economically and efficiently utilized for the improvement of the whole public health program? When the public health administrator has answered this question satisfactorily, he then will be in a position to utilize to advantage the services that a well qualified statistician is equipped to give.

Statistics in the Planning and Evaluation of Health Procedures*

HUGO MUENCH, M.D., DR.P.H., F.A.P.H.A.

Department of Biostatistics, Harvard School of Public Health, Boston, Mass.

THE statistician is primarily engaged in the business of measuring and counting. Measurements must be made on a recognized scale, and counts on items classified by accepted criteria. Moreover, such measurements and counts are made on populations subject to numerous kinds of variation, and it is one of the chief aims of statistical method to subject these variations to some sort of orderly process. This is all axiomatic and would doubtless earn the somewhat bored agreement of most statisticians.

We are all familiar with the variability encountered in measuring biological characteristics, be they the heights of a group of children or the amounts of hemoglobin per liter of their blood. We can describe the variations we expect to find in counting individuals or their attributes, and we are at all times conscious of this variability. There is another type of variability not so continually present in our thinking: the variation in the reliability of the information on which our counts are based.

What would we think of a physicist who gave us a series of measurements of wave lengths of light, based partly on the use of an interferometer and partly on that of a meter stick, and who, moreover, threw all his results into one table without discrimination? We should be entirely justified in asking him to

omit the latter group of readings, or at least to tabulate them separately, since their only effect on the more precise results would be to dilute them and to obscure the conclusions.

At the same time, we would not ask the physicist to use an interferometer to measure a group of babies. The added precision over the meter stick would not be worth the great deal of extra trouble; we should prefer a large number of measurements with the coarser instrument to a few highly refined observations for our purposes in this case, which would be the description of height characteristics of a population.

Variation in precision attaches to the different sorts of information gathered by statistical services. Some is subject to little misinterpretation and can be gathered by almost anyone with sufficient exactness to serve the purpose. This sort of information does not suffer from collection in large quantities, because it is not seriously stratified as to accuracy at different levels of information.

At the other end of the scale there is information so highly technical, so difficult to secure accurately, that only the most painstaking investigation will assure us of its reliability. This sort of information cannot be gathered anywhere, by anybody, with the same order of certainty. For best results, the data must be obtained from their most accurate source, no matter how limited, and they can only suffer if mixed with spurious figures.

* Presented before the Vital Statistics Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1946.

Along the middle of the scale of reliability is information which is perhaps not equally reliable at all sources, but which can be adjusted to some extent. In this way, an error introduced by the use of heterogeneous data may be compensated by the stability introduced through the use of a larger sample.

Quite properly, registration departments concern themselves with the most complete possible collection of certain items of information about people. The items are sorted and counted and any possible legitimate conclusions are drawn. Now these items of counted information range from the most indisputable of facts, through matters of informed opinion, to offhand guesses resting on foundations which are anything but secure. As long as we keep in mind which items fall into what categories, we are in no great danger; but we are at times inclined to forget.

Let us examine registration data in the light of a crude scale of reliability. On one hand, we have matters of fact yielding to no differences in interpretation—the fact of existence, for example. A person simply is here, or he is not, and there is very little room for argument. With proper diligence, plus considerable intelligence, we can keep a pretty fair record of how many people we have. We can also, with some accuracy, determine their sex, color, where they live, and (though less accurately) how old they are.

Items of this kind do not suffer by collection in large numbers, or not very much. There is little difference in their accuracy at different levels of reporting: life and death, male and female, Grand Boulevard and Hogan's Alley have about the same meaning for everybody. These are the sort of data which are most valuable when most nearly complete, because they are only very slightly tinged with qualitative error.

By their nature, these are the simple items of information, and we are not apt

to think of them as wildly exciting. We have accepted without comment for many years the fact that in improving our completeness of registration we have made more and more valuable the basic demographic data—which are reported with the highest accuracy. Now we have found that these data, when intelligently developed and used by a capable department of registration and analysis, are extraordinarily valuable not only to the administrator of a health department but to many other branches of government. Although development along these lines has been largely in urban areas, similar use should be possible and profitable in smaller and more rural departments.

As soon as we begin to depart from the clear concepts of existence, of birth and of death, we enter a hazier landscape where the edges of shadows are less sharply defined and distances are sometimes deceptive. The difficulties, for a while, are not great. We still deal with matters which are fairly clear and which are quite universally defined in the same manner. Some diseases would, for example, be diagnosed the same by almost any medical man and would, when so diagnosed quite uniformly appear on a death certificate. But the difference between having a disease (in its clinical form, at least) and not having it is nowhere nearly as sharp as that between life and death, nor is even the clearest concept of a disease as well defined as is that of sex.

By no means are all disease entities distinctly defined, nor are those of most frequent occurrence necessarily the most sharply differentiated. If you doubt this, ask the next ten physicians you meet to tell you how they would distinguish mild influenza, clinically, from a severe cold. You need not expect too much unanimity even though they may have been graduated from the same school at about the same time. Conversely, the fact that there is general agreement on the

assumption that a disease is a disease and not possibly a few other things, does not mean that it is necessarily easy to establish a diagnosis. This may require special training and a host of diagnostic aids which are not at the call of all practitioners in all parts of the country.

Old Doctor Jones, who could enter a patient's room and know, after one glance at the tongue, the cause of the trouble, has unfortunately gone the way of many heroes of a simpler day. He had, after all, very few diseases to contend with and his tools of diagnosis, consisting largely of experience and common sense, were as good as those most other physicians had at their command. But the list of diseases has multiplied enormously, and old clinical entities are being bombed into two or more totally unrelated fragments on every hand. Observe what has happened in the field of the pneumonias, which we once happily divided into "lobar" and "broncho." Not only has lobar pneumonia disintegrated into a nestful of diseases, distinct at least from the viewpoints of bacteriology and epidemiology, but a host of formerly unsuspected agents is giving us atypical pneumonias, virus pneumonias, and what not. Worst of all, we cannot even hope to diagnose or distinguish them without x-rays and a modern virus laboratory.

It does not give us much specific information to lump all these entities into a group designated "other pneumonias," and it is obviously impossible to separate them without processes requiring special skills. In order to count something we must first identify it, and if its identification can be made only in special fields, then those are the only fields from which we can get reliable data. Adding a great number of items based on uncertain diagnostic methods to a small nucleus of well defined cases does not add to information, it hopelessly

clouds any conclusions we might draw from the smaller group. Yet we are apt to prefer the larger number, perhaps because we unconsciously assign to it a combination of the precision of the smaller group and the statistical stability of the larger.

If we stop to think, we must realize that medical diagnosis is definitely stratified into many areas of reliability. It is higher in a university teaching hospital with a large, trained staff than in even a very good private hospital. The city man, to whom specialized diagnostic aids are readily accessible, will on the whole make more accurately refined diagnoses than will his equally able country colleague. In our accumulated mortality and morbidity data we make little effort to stratify our information in accord with its reliability, but this variable cannot but enter into any comparisons which may be made.
